Algorithms

Reminder: **directed graphs** are graphs where...

- Each edge (v, w) has a **source** v and a **destination** w
- Unlike undirected graphs, $v \rightarrow w \neq w \rightarrow v$

Traversal

Transitive
ClosureOther
Algorithms

application	vertex is...	edge is...
WWW	web page	hyperlink
chess	board state	legal move
scheduling	task	precedence
program	function	function call
journals	article	citation
make	target	dependency

Same as for undirected graphs:

```
bfs( $G, src$ ):  
    initialise visited array  
    mark  $src$  as visited  
    enqueue  $src$  into  $Q$   
    while  $Q$  is not empty:  
         $v =$  dequeue from  $Q$   
        for each edge  $(v, w)$  in  $G$ :  
            if  $w$  has not been visited:  
                mark  $w$  as visited  
                enqueue  $w$  into  $Q$ 
```

```
dfs( $G, src$ ):  
    initialise visited array  
    dfsRec( $G, src, visited$ )
```

```
dfsRec( $G, v, visited$ ):  
    mark  $v$  as visited  
    for each edge  $(v, w)$  in  $G$ :  
        if  $w$  has not been visited:  
            dfsRec( $G, w, visited$ )
```

Web crawling

Visit a subset of the web...

...to index

...to cache locally

Which traversal method? BFS or DFS?

Note: we can't use a visited array, as we don't know how many webpages there are. Instead, use a visited **set**.

Web crawling algorithm:

```
webCrawl(startingUrl, maxPagesToVisit):
```

```
    create visited set
```

```
    add startingUrl to visited set
```

```
    enqueue startingUrl into  $Q$ 
```

```
    numPagesVisited = 0
```

```
    while  $Q$  is not empty and numPagesVisited < maxPagesToVisit:
```

```
        currPage = dequeue from  $Q$ 
```

```
        visit currPage
```

```
        numPagesVisited = numPagesVisited + 1
```

```
        for each hyperlink on currPage:
```

```
            if hyperlink not in visited set:
```

```
                add hyperlink to visited set
```

```
                enqueue hyperlink into  $Q$ 
```

Problem: computing **reachability**

Given a digraph G it is potentially useful to know:

- Is vertex t **reachable** from vertex s ?

One way to implement a reachability check:

- Use BFS or DFS starting at s
 - This is $O(V + E)$ in the worst case
 - Only feasible if reachability is an infrequent operation

What about applications that frequently need to check reachability?

Idea

Construct a $V \times V$ matrix
that tells us whether there is a **path** (not edge)
from s to t , for $s, t \in V$

This matrix is called the **transitive closure** (tc) matrix
(or reachability matrix)

$tc[s][t]$ is true if there is a path from s to t , false otherwise

Idea of Warshall's algorithm:

- There is a path from s to t if:
 - There is an edge from s to t , or
 - There is a path from s to t via vertex 0 only, or
 - There is a path from s to t via vertex 0 and/or 1 only, or
 - There is a path from s to t via vertex 0, 1 and/or 2 only, or
 - ...
 - There is a path from s to t via any of the vertices

Example:

- There is a path from s to t if:
 - There is an edge from s to t , or

Example:

- There is a path from s to t if:
 - There is an edge from s to t , or
 - There is a path from s to t via vertex 0 only, or

Example:

- There is a path from s to t if:
 - There is an edge from s to t , or
 - There is a path from s to t via vertex 0 only, or
 - There is a path from s to t via vertex 0 and/or 1 only, or

Example:

- There is a path from s to t if:
 - There is an edge from s to t , or
 - There is a path from s to t via vertex 0 only, or
 - There is a path from s to t via vertex 0 and/or 1 only, or
 - There is a path from s to t via vertex 0, 1 and/or 2 only, or

Example:

- There is a path from s to t if:
 - There is an edge from s to t , or
 - There is a path from s to t via vertex 0 only, or
 - There is a path from s to t via vertex 0 and/or 1 only, or
 - There is a path from s to t via vertex 0, 1 and/or 2 only, or
 - There is a path from s to t via vertex 0, 1, 2 and/or 3

Algorithms

On the k -th iteration, the algorithm determines if a path exists between two vertices s and t using just $0, \dots, k$ as intermediate vertices

On the k -th iteration

If we have:

- (1) a path from s to k
 - (2) a path from k to t
- (using only vertices 0 to $k - 1$)

On the k -th iteration, the algorithm determines if a path exists between two vertices s and t using just $0, \dots, k$ as intermediate vertices

On the k -th iteration

If we have:

- (1) a path from s to k
 - (2) a path from k to t
- (using only vertices 0 to $k - 1$)

Then we have a path from s to t
using vertices from 0 to k

```
if tc[s][k] and tc[k][t]:  
    tc[s][t] = true
```

Other
Algorithms

Analysis:

- Time complexity: $O(V^3)$
 - Three nested loops iterating over all vertices
- Space complexity: $O(V^2)$
 - Can be $O(1)$ if overwriting the input matrix
- Benefit: checking reachability between vertices is now $O(1)$
 - Makes up for slow setup ($O(V^3)$) if reachability is a very frequent operation
