## Security II

COMP3231

## Security Policy & Mechanisms

- · Policy decides what kinds of entities can perform operations on what kinds of objects
  - Deals with users, processes, students, files, printers, managers
    - Example: Students can't use the colour printer
- Protection mechanisms are used to represent and enforce security policy
  - Example: reference monitor looks up a table representing a policy and decided yes/no.

COMP3231

#### **Protection Mechanisms**

- Protection system deals with
  - Objects
    - Set of 'things' in the system that can be operated on
      - Files, devices, sockets, etc...
  - - The permission to perform one of the operations possible on an object
      - Example: Possessing permission to read an object is termed possessing a read right to the object.
  - Domains
    - A set of (object, right) pairs which together represent the set of possible operations on objects.
    - · Each process has a domain associated with it.

COMP3231

#### **Protection Domains** Domain 2 File1[R] File3[R] File6[RWX] File4[RWX] File5[RW] Printer1[W] File2[RW] Plotter2[W] Examples of three protection domains COMP3231 THE UNIVERSITY OF NEW SOUTH WALES

### **Protection Domain Example**

- UNIX
  - The UID and GID of a process determines the domain the process executes within
    - Determines exactly what rights the process has to objects (files) in the system
  - Another process with the same UID, GID lies with the same domain
    - · Has exactly the same set of access rights to objects
  - Process can change domains to gain access rights via SETUID or SETGUID

COMP3231

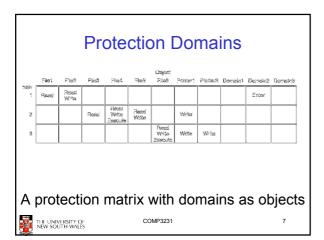

## Representing Protection Domains

	Object							
	File1	File2	File3	File4	File5	File6	Printer1	Plotter2
Domain 1	Read	Read Write						
2			Read	Read Write Execute	Read Write		Write	
3						Read Write Execute	Write	Write

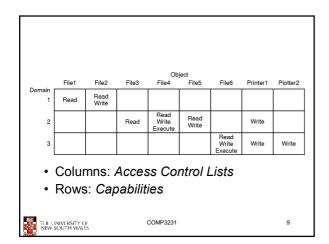

Represent access rights using a protection matrix

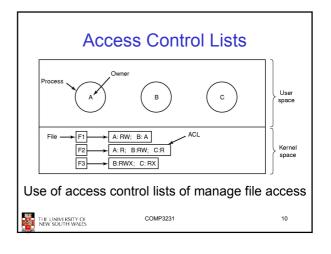

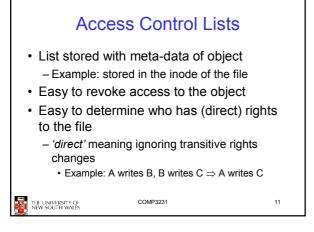

COMP3231

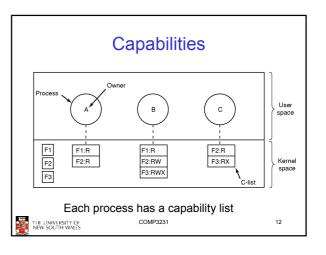

#### Capabilities

- Capability list stored with the subject (e.g. the process)
- Set of capabilities forms the protection of domain of the subject
  - Easy to determine the protection domain of the process
  - Easier to apply principle of least authority
- Hard to determine who has (direct) access to a particular object
  - Capabilities can be stored many places (with each process, each user, etc..)
  - Have to examine them all for one referring to the object
- · Revocation is more difficult (especially selective)
  - Have to remove all capabilities to an object

COMP3231

13

15

#### **Summary**

- Protections mechanisms deal with domains, objects, access rights
- Can use a protection matrix to represent a security policy
- Protection matrix can be represented by ACLs or Capabilities

COMP3231

14

#### **Building Secure Systems**

- · Sometimes called Trusted Systems
- Consist on users/processes running on Trusted Computing Base (TCB)
- Idea
  - TCB has a small, understandable, verifiable, security model
  - Enables statements/reasoning about security properties
    - "Bob can never read file X"
    - "Alice can only run the word processor"
    - "The program can only modify file Z"
  - All operations are authorised via the TCB.

COMP3231

Trusted Systems
Trusted Computing Base

User process

All system calls go through the reference monitor for security checking

Reference monitor

Trusted computing base
Operating system kernel

A reference monitor

COMP3231

16

#### Formal Models of Secure Systems Objects Objects Compiler Mailbox 7 Mailbox 7 Read Read Eric Read Execute Read Read Read Read Write Read (b) An unauthorized state (Robert can read Henry's mailbox) Given a set of authorized and unauthorized states, and the TCB's security model, can we prove that starting at (a), (b) can never happen?? COMP3231 17 THE UNIVERSITY OF NEW SOUTH WALES

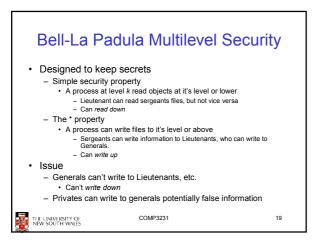

#### **Access Control Policy**

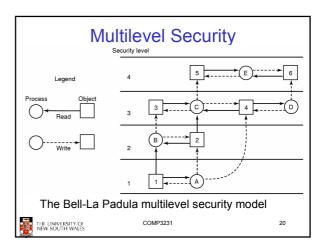

- Discretionary Access Control
  - Allow users to determine who can read and write their files
  - Policy not enough to control information flow
  - Example: UNIX
- · Mandatory Access Control
  - System determines (and enforced) who can read and write individual files
  - Example policies: Bell-La Padula and Biba

COMP3231

18

#### Multilevel Security The Biba Model

- Principles to guarantee integrity of data
- 1. Simple integrity principle
  - process can write only objects at its security level or
- 2. The integrity \* property
  - process can read only objects at its security level or higher

21

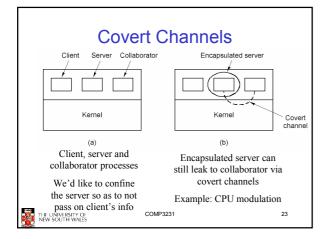

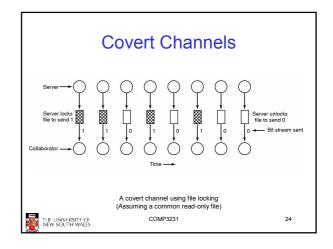

# Multilevel Security

The Biba Model

- Managers can write the files of employees
- Employees cannot write the files of managers
- Employees read (trust) files of managers
- Managers cannot read (trust) the files of employees
- Note: Biba and Bell-La Padula are in direct conflict with each other
  - Developing and formalising a realistic and practical security policy is hard

# **Covert Channels**

- Can be created using a any shared resource whose behaviour can be monitored
  - Network Bandwidth
  - CPU time
  - Disk Response time
  - Disk Bandwidth
