Virtual Memory II
TLB Recap

• Fast associative cache of page table entries
  – Contains a subset of the page table
  – What happens if required entry for translation is not present (a *TLB miss*)?
TLB Recap

• TLB may or may not be under OS control
  – Hardware-loaded TLB
    • On miss, hardware performs PT lookup and reloads TLB
    • Example: Pentium
  – Software-loaded TLB
    • On miss, hardware generates a TLB miss exception, and exception handler reloads TLB
    • Example: MIPS
Aside: even if filled by software

- TLB still a hardware translator
R3000 TLB Handling

- TLB refill is handled by software
  - An exception handler
- TLB refill exceptions accessing kuseg are expected to be frequent
  - CPU optimised for handling kuseg TLB refills by having a special exception handler just for TLB refills
## Exception Vectors

Table 4.1. Reset and exception vectors (for R30xx family)
Special Exception Vector

- Can be optimised for TLB refill only
  - Does not need to check the exception type
  - Does not need to save any registers
    - It uses a specialised assembly routine that only uses k0 and k1.
  - Does not check if PTE exists
    - Assumes virtual linear array – see extended OS notes

- With careful data structure choice, exception handler can be made very fast

- An example routine
  
  ```
  mfc0 k1, C0_CONTEXT
  mfc0 k0, C0_EPC # mfc0 delay
  # slot
  lw k1, 0(k1) # may double
  # fault (k0 = orig EPC)
  nop
  mtc0 k1, C0_ENTRYLO
  nop
  tlbwr
  jr k0
  rfe
  ```
MIPS VM Related Exceptions

- **TLB refill**
  - Handled via special exception vector
  - Needs to be very fast

- **Others handled by the general exception vector**
  - **TLB Mod**
    - TLB modify exception, attempt to write to a read-only page
  - **TLB Load**
    - Attempt it load from a page with an invalid translation
  - **TLB Store**
    - Attempt to store to a page with an invalid translation
  - **Note:** these can be slower as they are mostly either caused by an error, or non-resident page.
    - We never optimise for errors, and page-loads from disk dominate the fault resolution cost.
<Intermezzo>
Amdahl’s law

- States that overall performance improvement is limited by the fraction of time an enhancement can be used.

Law of diminishing returns

\[
\begin{align*}
\text{Time}_{\text{old}} &= 50 \quad 50 \\
\Rightarrow \\
\text{Time}_{\text{new}} &= 50 \quad 25
\end{align*}
\]

Fraction in enhanced mode = 0.5 (based on old system)

Speedup of enhanced mode = 2
Amdahl’s law

- States that overall performance improvement is limited by the fraction of time an enhancement can be used
</Intermezzo>
c0 Registers

- **c0_EPC**
  - The address of where to restart after the exception
- **c0_status**
  - Kernel/User Mode bits, Interrupt control
- **c0_cause**
  - What caused the exception
- **c0_badvaddr**
  - The address of the fault
The TLB and EntryHi, EntryLo

Each TLB entry contains
- EntryHi to match page# and ASID
- EntryLo which contains frame# and protection

Used to read and write individual TLB entries
### c0 Registers

<table>
<thead>
<tr>
<th>Field</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>VPN</td>
<td>31</td>
</tr>
<tr>
<td>ASID</td>
<td>12</td>
</tr>
<tr>
<td>N</td>
<td>11</td>
</tr>
<tr>
<td>D</td>
<td>6</td>
</tr>
<tr>
<td>V</td>
<td>5</td>
</tr>
<tr>
<td>N</td>
<td>0</td>
</tr>
</tbody>
</table>

**EntryHi Register (TLB key fields)**

**EntryLo Register (TLB data fields)**

- **N** = Not cacheable
- **D** = Dirty = Write protect
- **G** = Global (ignore ASID in lookup)
- **V** = valid bit
- **64 TLB entries**
- **Accessed via software through Cooprocessor 0 registers**
  - EntryHi and EntryLo
c0 Index Register

- Used as an index to TLB entries
  - Single TLB entries are manipulated/viewed through EntryHi and EntryLo0
  - Index register specifies which TLB entry to change/view
Special TLB management Instructions

- **TLBR**
  - TLB read
    - EntryHi and EntryLo are loaded from the entry pointer to by the index register.

- **TLBP**
  - TLB probe
    - Set EntryHi to the entry you wish to match, index register is loaded with the index to the matching entry

- **TLBWR**
  - Write EntryHi and EntryLo to a psuedo-random location in the TLB

- **TLBWI**
  - Write EntryHi and EntryLo to the location in the TLB pointed to by the Index register.
Coprocessor 0 registers on a refill exception

c0.EPC ← PC

c0.cause.ExcCode ← TLBL ; if read fault

c0.cause.ExcCode ← TLBS ; if write fault

c0.BadVaddr ← faulting address

c0.EntryHi.VPN ← faulting address

c0.status ← kernel mode, interrupts disabled.

c0.PC ← 0x8000 0000
Outline of TLB miss handling

• Software does:
  – Look up PTE corresponding to the faulting address
  – If found:
    • load c0_EntryLo with translation
    • load TLB using TLBWR instructions
    • return from exception
  – Else, page fault

• The TLB entry (i.e. c0_EntryLo) can be:
  – created on the fly, or
  – stored completely in the right format in page table
    • more efficient
OS/161 Refill Handler

• After switch to kernel stack, it simply calls the common exception handler
  – Stacks all registers
  – Can (and does) call ‘C’ code
  – Unoptimised
  – Goal is ease of kernel programming, not efficiency

• Does not have a page table
  – It uses the 64 TLB entries and then panics when it runs out.
    • Only support 256K user-level address space
Demand
Paging/Segmentation
Demand Paging/Segmentation

• With VM, only parts of the program image need to be resident in memory for execution.
• Can transfer presently unused pages/segments to disk
• Reload non-resident pages/segment on demand.
  – Reload is triggered by a page or segment fault
  – Faulting process is blocked and another scheduled
  – When page/segment is resident, faulting process is restarted
  – May require freeing up memory first
    • Replace current resident page/segment
    • How determine replacement “victim”?
  – If victim is unmodified (“clean”) can simply discard it
    • This is reason for maintaining a “dirty” bit in the PT
• Why does demand paging/segmentation work?
  – Program executes at full speed only when accessing the resident set.
  – TLB misses introduce delays of several microseconds
  – Page/segment faults introduce delays of several milliseconds
  – Why do it?

• Answer
  – Less physical memory required per process
    • Can fit more processes in memory
    • Improved chance of finding a runnable one
  – Principle of locality
Principle of Locality

• An important observation comes from empirical studies of the properties of programs.
  – Programs tend to reuse data and instructions they have used recently.
  – **90/10 rule**
    "A program spends 90% of its time in 10% of its code"

• We can exploit this **locality of references**

• An implication of locality is that we can reasonably predict what **instructions** and **data** a program will use in the near future based on its accesses in the recent past.
• **Two different types** of locality have been observed:
  – *Temporal* locality: states that recently accessed items are likely to be accessed in the near future.
  – *Spatial* locality: says that items whose addresses are near one another tend to be referenced close together in time.
Locality In A Memory-Reference Pattern
Working Set

• The pages/segments required by an application in a time window ($\Delta$) is called its memory *working set*.

• Working set is an approximation of a program’s locality
  – if $\Delta$ too small will not encompass entire locality.
  – if $\Delta$ too large will encompass several localities.
  – if $\Delta = \infty \Rightarrow$ will encompass entire program.
  – $\Delta$’s size is an application specific tradeoff

• System should keep resident at least a process’s working set
  – Process executes while it remains in its working set

• Working set tends to change gradually
  • Get only a few page/segment faults during a time window
  • Possible to make intelligent guesses about which pieces will be needed in the future
    – May be able to pre-fetch page/segments
Working Set Model
Thrashing

- CPU utilisation tends to increase with the degree of multiprogramming
  - number of processes in system
- Higher degrees of multiprogramming – less memory available per process
- Some process’s working sets may no longer fit in RAM
  - Implies an increasing page fault rate
- Eventually many processes have insufficient memory
  - Can’t always find a runnable process
  - Decreasing CPU utilisation
  - System become I/O limited
- This is called **thrashing**.
Thrashing

- Why does thrashing occur?
  \[ \sum \text{working set sizes} > \text{total physical memory size} \]
Recovery From Thrashing

• In the presence of increasing page fault frequency and decreasing CPU utilisation
  – Suspend a few processes to reduce degree of multiprogramming
  – Resident pages of suspended processes will migrate to backing store
  – More physical memory becomes available
    • Less faults, faster progress for runnable processes
  – Resume suspended processes later when memory pressure eases
Quiz

• how does an IPT work?
  – what is good about it?
  – what is bad about it?
• what is the TLB?
  – what happens on a context switch?
• what is a working set?
• what is thrashing?
What is the difference?

/* reset array */
int array[10000][10000];
int i,j;
for (i = 0; i < 10000; i++) {
    for (j = 0; j < 10000; j++) {
        array[i][j] = 0; /* array[j][i] = 0 */
        Array[a][b]
    }
}

THE UNIVERSITY OF NEW SOUTH WALES
VM Management Policies
VM Management Policies

- Operation and performance of VM system is dependent on a number of policies:
  - Page table format (may be dictated by hardware)
    - Multi-level
    - Hashed
  - Page size (may be dictated by hardware)
  - Fetch Policy
  - Replacement policy
  - Resident set size
    - Minimum allocation
    - Local versus global allocation
  - Page cleaning policy
  - Degree of multiprogramming
Page Size

Increasing page size

✗ Increases internal fragmentation
  ▪ reduces adaptability to working set size

✓ Decreases number of pages
  ▪ Reduces size of page tables

✓ Increases TLB coverage
  ▪ Reduces number of TLB misses

✗ Increases page fault latency
  ▪ Need to read more from disk before restarting process

✓ Increases swapping I/O throughput
  ▪ Small I/O are dominated by seek/rotation delays
  ▪ Optimal page size is a (work-load dependent) trade-off.

Page Size

• Multiple page sizes provide flexibility to optimise the use of the TLB

• Example:
  – Large page sizes can be use for code
  – Small page size for thread stacks

• Most operating systems support only a single page size
  – Dealing with multiple page sizes is hard!
Fetch Policy

• Determines when a page should be brought into memory
  – *Demand paging* only loads pages in response to page faults
    • Many page faults when a process first starts
  – *Pre-paging* brings in more pages than needed at the moment
    • Improves I/O performance by reading in larger chunks
    • Pre-fetch when disk is idle
    • Wastes I/O bandwidth if pre-fetched pages aren’t used
    • Especially bad if we eject pages in working set in order to pre-fetch unused pages.
    • Hard to get right in practice.
Page fault on page 14, physical memory full, which page should we evict?
Replacement Policy

• Which page is chosen to be tossed out?
  – Page removed should be the page least likely to be references in the near future
  – Most policies attempt to predict the future behaviour on the basis of past behaviour

• Constraint: locked frames
  – Kernel code
  – Main kernel data structure
  – I/O buffers
  – Performance-critical user-pages (e.g. for DBMS)

• Frame table has a lock bit
**Optimal Replacement policy**

- Toss the page that won’t be used for the longest time
- Impossible to implement
- Only good as a theoretic reference point:
  - The closer a practical algorithm gets to *optimal*, the better
- Example:
  - Reference string: 1, 2, 3, 4, 1, 2, 5, 1, 2, 3, 4, 5
  - Four frames
  - How many page faults?
FIFO Replacement Policy

• First-in, first-out: Toss the oldest page
  – Easy to implement
  – Age of a page is isn’t necessarily related to usage

• Example:
  – Reference string: 1,2,3,4,1,2,5,1,2,3,4,5
  – Four frames
  – How many page faults?
  – Three frames?
Belady’s Anomaly

• More frames does not imply fewer page faults
Least Recently Used (LRU)

• Toss the least recently used page
  – Assumes that page that has not been referenced for a long time is unlikely to be referenced in the near future
  – Will work if locality holds
  – Implementation requires a time stamp to be kept for each page, updated on every reference
  – Impossible to implement efficiently
  – Most practical algorithms are approximations of LRU
Clock Page Replacement

• Clock policy, also called second chance
  – Employs a usage or reference bit in the frame table.
  – Set to one when page is used
  – While scanning for a victim, reset all the reference bits
  – Toss the first page with a zero reference bit.
Figure 8.16 Example of Clock Policy Operation
Figure 8.16  Example of Clock Policy Operation

Assume a page fault on page 727

(a) State of buffer just prior to a page replacement
(b) State of buffer just after the next page replacement

Figure 8.16 Example of Clock Policy Operation
Issue

• How do we know when a page is referenced?
• Use the valid bit in the PTE:
  – When a page is mapped (valid bit set), set the reference bit
  – When resetting the reference bit, invalidate the PTE entry
  – On page fault
    • Turn on valid bit in PTE
    • Turn on reference bit
• We thus simulate a reference bit in software
Performance

• In terms of selecting the most appropriate replacement, they rank as follows:
  1. Optimal
  2. LRU
  3. Clock
  4. FIFO

  – Note there are other algorithms (Working Set, WSclock, Ageing, NFU, NRU)
  – We don’t expect you to know them in this course
Resident Set Size

• How many frames should each process have?
  – *Fixed Allocation*
    • Gives a process a fixed number of pages within which to execute.
    • When a page fault occurs, one of the pages of that process must be replaced.
    • Achieving high utilisation is an issue.
      – Some processes have high fault rate while others don’t use their allocation.
  – *Variable Allocation*
    • Number of pages allocated to a process varies over the lifetime of the process
Variable Allocation, Global Scope

- Easiest to implement
- Adopted by many operating systems
- Operating system keeps global list of free frames
- Free frame is added to resident set of process when a page fault occurs
- If no free frame, replaces one from any process
Variable Allocation, Local Scope

- Allocate number of page frames to a new process based on
  - Application type
  - Program request
  - Other criteria (priority)
- When a page fault occurs, select a page from among the resident set of the process that suffers the page fault
- Re-evaluate allocation from time to time!
Page-Fault Frequency Scheme

- Establish “acceptable” page-fault rate.
  - If actual rate too low, process loses frame.
  - If actual rate too high, process gains frame.
Cleaning Policy

• Observation
  – Clean pages are much cheaper to replace than dirty pages

• Demand cleaning
  – A page is written out only when it has been selected for replacement
  – High latency between the decision to replace and availability of free frame.

• Precleaning
  – Pages are written out in batches (in the background, the pagedaemon)
  – Increases likelihood of replacing clean frames
  – Overlap I/O with current activity
Load Control (Degree of multiprogramming)

• Determines the number of runnable processes
• Controlled by:
  – Admission control
    • Only let new process’s threads enter *ready* state if enough memory is available
  – Suspension:
    • Move all threads of some process into a special *suspended* state
    • Swap complete process image of suspended process to disk
• Trade-off
  – Too many processes will lead to thrashing
  – Too few will lead to idle CPU or excessive swapping
Load Control Considerations

- Can use page fault frequency.
