I/O Management
Software

Chapter 5
Operating System Design Issues

• **Efficiency**
  - Most I/O devices slow compared to main memory (and the CPU)
    • Use of multiprogramming allows for some processes to be waiting on I/O while another process executes
    • Often I/O still cannot keep up with processor speed
    • Swapping may used to bring in additional Ready processes
      – More I/O operations

• **Optimise I/O efficiency – especially Disk & Network I/O**
Operating System Design

Issues

• The quest for generality/uniformity:
  – Ideally, handle all I/O devices in the same way
    • Both in the OS and in user applications
  – Problem:
    • Diversity of I/O devices
    • Especially, different access methods (random access versus stream based) as well as vastly different data rates.
    • Generality often compromises efficiency!
  – Hide most of the details of device I/O in lower-level routines so that processes and upper levels see devices in general terms such as read, write, open, close.
I/O Software Layers

Layers of the I/O Software System

- User-level I/O software
- Device-independent operating system software
- Device drivers
- Interrupt handlers
- Hardware
Interrupt Handlers

- **Interrupt handlers**
  - Can execute at (almost) any time
    - Raise (complex) concurrency issues in the kernel
    - Can propagate to userspace (signals, upcalls), causing similar issues
    - Generally structured so I/O operations block until interrupts notify them of completion
      - kern/dev/lamebus/lhd.c
Interrupt Handler Example

static int 
lhd_io(struct device *d, 
    struct uio *uio)
{
    ...
/* Loop over all the sectors */
    for (i=0; i<len; i++) {
/* Wait until nobody else */
    P(lh->lh_clear);
    ...
/* Tell it what sector we want... */
lhd_wreg(lh, LHD_REG_SECT, sector+i);
/* and start the operation. */
lhd_wreg(lh, LHD_REG_STAT, statval);
/* Now wait until the interrupt */
    P(lh->lh_done);
/* Get the result value */
    result = lh->lh_result;
}

lhd_iodeone(struct lhd_softc *lh, int err) 
{
    lh->lh_result = err;
    V(lh->lh_done);
}

void 
lhd_irq(void *vlh)
{
    ...
    val = lhd_rdreg(lh, LHD_REG_STAT);
    switch (val & LHD_STATEMASK) {
    case LHD_IDLE:
        break;
    case LHD_WORKING:
        break;
    case LHD_OK:
    case LHD_INVSECT:
    case LHD_MEDIA:
        lhd_wreg(lh, LHD_REG_STAT, 0);
        lhd_iodeone(lh, 
            lhd_code_to_errno(lh, val));
        break;
    }
}
Interrupt Handler Steps

- **Save Registers** not already saved by hardware interrupt mechanism

- (Optionally) **set up context** for interrupt service procedure
  - Typically, handler runs in the context of the currently running process
    - No expensive context switch

- **Set up stack** for interrupt service procedure
  - Handler usually runs on the kernel stack of current process

- **Ack/Mask interrupt controller**, re-enable other interrupts
  - What does this imply?
Interrupt Handler Steps

• **Run interrupt service procedure**
  – Acknowledges interrupt at device level
  – Figures out what caused the interrupt
    • Received a network packet, disk read finished, UART transmit queue empty
  – If needed, it signals blocked device driver

• **In some cases, will have woken up a higher priority blocked thread**
  – Choose newly woken thread to schedule next.
  – Set up MMU context for process to run next
  – What if we are nested?

• **Load new/original process' registers**

• **Re-enable interrupt:** Start running the new process
Sleeping in Interrupts

• Interrupt generally has no context (runs on current stack)
  – Unfair to sleep interrupted process (deadlock possible)
  – Where to get context for long running operation?
  – What goes into the ready queue?

• What to do?
  – Top and Bottom Half
  – Linux implements with tasklets and workqueues
  – Generically, in-kernel thread(s) handle long running kernel operations.
• Logical position of device drivers is shown here
• Drivers (originally) compiled into the kernel
  – Including OS/161
  – Device installers were technicians
  – Number and types of devices rarely changed
• Nowadays they are dynamically loaded when needed
  – Linux modules
  – Typical users (device installers) can’t build kernels
  – Number and types vary greatly
    • Even while OS is running (e.g., hot-plug USB devices)
Device Drivers

• Drivers classified into similar categories
  – Block devices and character (stream of data) device

• OS defines a standard (internal) interface to the different classes of devices
  – Device specs often help, e.g. USB

• Device drivers job
  – translate request through the device-independent standard interface (open, close, read, write) into appropriate sequence of commands (register manipulations) for the particular hardware
  – Initialise the hardware at boot time, and shut it down cleanly at shutdown
Device Driver

- After issuing the command to the device, the device either
  - Completes immediately and the driver simply returns to the caller
  - Or, the device must process the request and the driver usually blocks waiting for an I/O complete interrupt.
- Drivers are re-entrant as they can be called by another process while a process is already blocked in the driver.
  - Re-entrant: Code that can be executed by more than one thread (or CPU) at the same time
    - Manages concurrency using synch primitives
Device-Independent I/O Software

• There is commonality between drivers of similar classes
• Divide I/O software into device-dependent and device-independent I/O software
• Device independent software includes
  – Buffer or Buffer-cache management
  – Managing access to dedicated devices
  – Error reporting
Device-Independent I/O Software

(a) Without a standard driver interface
(b) With a standard driver interface
Driver ⇔ Kernel Interface

• Major Issue is uniform interfaces to devices and kernel
  – Uniform device interface for kernel code
    • Allows different devices to be used the same way
      – No need to rewrite file-system to switch between SCSI, IDE or RAM disk
    • Allows internal changes to device driver with fear of breaking kernel code
  – Uniform kernel interface for device code
    • Drivers use a defined interface to kernel services (e.g. kmalloc, install IRQ handler, etc.)
    • Allows kernel to evolve without breaking existing drivers
  – Together both uniform interfaces avoid a lot of programming implementing new interfaces
Device-Independent I/O Software

(a) Unbuffered input
(b) Buffering in user space
(c) *Single buffering* in the kernel followed by copying to user space
(d) Double buffering in the kernel
No Buffering

• Process must read/write a device a byte/word at a time
  – Each individual system call adds significant overhead
  – Process must what until each I/O is complete
    • Blocking/interrupt/waking adds to overhead.
    • Many short runs of a process is inefficient (poor CPU cache temporal locality)
User-level Buffering

• Process specifies a memory buffer that incoming data is placed in until it fills
  – Filling can be done by interrupt service routine
  – Only a single system call, and block/wakeup per data buffer
    • Much more efficient
User-level Buffering

• Issues
  – What happens if buffer is paged out to disk
    • Could lose data while buffer is paged in
    • Could lock buffer in memory (needed for DMA), however many processes doing I/O reduce RAM available for paging. Can cause deadlock as RAM is limited resource
  – Consider write case
    • When is buffer available for re-use?
      – Either process must block until potential slow device drains buffer
      – or deal with asynchronous signals indicating buffer drained
Single Buffer

• Operating system assigns a buffer in main memory for an I/O request
• Stream-oriented
  – Used a line at a time
  – User input from a terminal is one line at a time with carriage return signaling the end of the line
  – Output to the terminal is one line at a time
Single Buffer

• Block-oriented
  – Input transfers made to buffer
  – Block moved to user space when needed
  – Another block is moved into the buffer
    • Read ahead
Single Buffer

– User process can process one block of data while next block is read in
– Swapping can occur since input is taking place in system memory, not user memory
– Operating system keeps track of assignment of system buffers to user processes
Single Buffer Speed Up

• Assume
  – $T$ is transfer time for a block from device
  – $C$ is computation time to process incoming block
  – $M$ is time to copy kernel buffer to user buffer

• Computation and transfer can be done in parallel

• Speed up with buffering

$$\frac{T + C}{\max(T, C) + M}$$
Single Buffer

• What happens if kernel buffer is full, the user buffer is swapped out, and more data is received???
  – We start to lose characters or drop network packets
Double Buffer

- Use two system buffers instead of one
- A process can transfer data to or from one buffer while the operating system empties or fills the other buffer
Double Buffer Speed Up

- Computation and Memory copy can be done in parallel with transfer
- Speed up with double buffering

\[ \frac{T + C}{\max(T, C + M)} \]

- Usually M is much less than T giving a favourable result
Double Buffer

- May be insufficient for really bursty traffic
  - Lots of application writes between long periods of computation
  - Long periods of application computation while receiving data
  - Might want to read-ahead more than a single block for disk
Circular Buffer

- More than two buffers are used
- Each individual buffer is one unit in a circular buffer
- Used when I/O operation must keep up with process
Important Note

- Notice that buffering, double buffering, and circular buffering are all Bounded-Buffer Producer-Consumer Problems
Is Buffering Always Good?

\[ \frac{T + C}{\max(T, C) + M} \]

Single

\[ \frac{T + C}{\max(T, C + M)} \]

Double

- Can \( M \) be similar or greater than \( C \) or \( T \)?
Buffering in Fast Networks

- Networking may involve many copies
- Copying reduces performance
  - Especially if copy costs are similar to or greater than computation or transfer costs
- Super-fast networks put significant effort into achieving zero-copy
- Buffering also increases latency
I/O Software Summary

Layers of the I/O system and the main functions of each layer

User processes
- Make I/O call; format I/O; spooling

Device-independent software
- Naming, protection, blocking, buffering, allocation

Device drivers
- Set up device registers; check status

Interrupt handlers
- Wake up driver when I/O completed

Interrupt handlers
- Perform I/O operation

Hardware

Layer

I/O request

I/O reply

I/O functions
