

Case study: ext2 FS

1

The ext2 file system

- Second Extended Filesystem
 - The main Linux FS before ext3
 - Evolved from Minix filesystem (via "Extended Filesystem")
- Features
 - Block size (1024, 2048, and 4096) configured at FS creation
 - inode-based FS
 - Performance optimisations to improve locality (from BSD FFS)
- Main Problem: unclean unmount → **e2fsck**
 - Ext3fs keeps a journal of (meta-data) updates
 - Journal is a file where updates are logged
 - Compatible with ext2fs

Recap: i-nodes

- Each file is represented by an inode on disk
- Inode contains the fundamental file metadata
 - Access rights, owner, accounting info
 - (partial) block index table of a file
- Each inode has a unique number
 - System oriented name
 - Try 'ls -li' on Unix (Linux)
- Directories map file names to inode numbers
 - Map human-oriented to system-oriented names

3

Recap: i-nodes

Ext2 i-nodes

mode

triple indirect	4

•Single Indirect Block
–Block number of a block containing block numbers

28	0		10				7
29	3	8		4			
38	SI						11
46	0	9	17	5	15		
61							
43	56	1			16	6	63

Disk 13

Single Indirection

- Requires two disk access to read
 - One for the indirect block; one for the target block
- Max File Size
 - Assume 1Kbyte block size, 4 byte block numbers
 - $12 * 1K + 1K/4 * 1K = 268 \text{ KiB}$
- For large majority of files (< 268 KiB), given the inode, only one or two further accesses required to read any block in file.

triple indirect

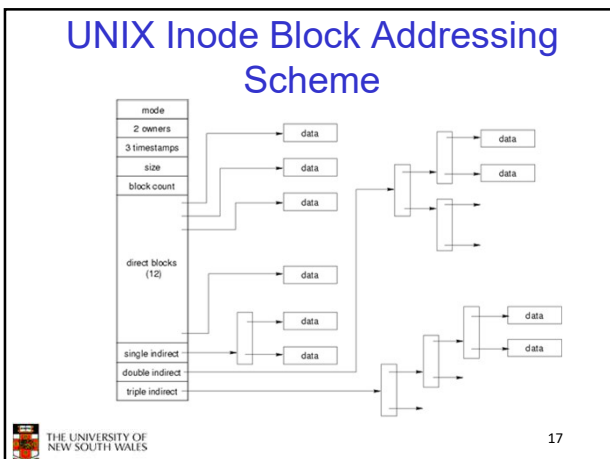

•Double Indirect Block
–Block number of a block containing block numbers of blocks containing block numbers

•Triple Indirect
–Block number of a block containing block numbers of blocks containing block numbers of blocks containing block numbers ☺

UNIX Inode Block Addressing Scheme

- Assume 8 byte blocks, containing 4 byte block numbers
- => each block can contain 2 block numbers (1-bit index)
- Assume a single direct block number in inode

Max File Size

- Assume 4 bytes block numbers and 1K blocks
- The number of addressable blocks
 - Direct Blocks = 12
 - Single Indirect Blocks = 256
 - Double Indirect Blocks = 256 * 256 = 65536
 - Triple Indirect Blocks = 256 * 256 * 256 = 16777216
- Max File Size

$$12 + 256 + 65536 + 16777216 = 16843020 \text{ blocks} = 16 \text{ GB}$$

Where is the data block number stored?

- Assume 4K blocks, 4 byte block numbers, 12 direct blocks
- A 1 byte file produced by
 - `lseek(fd, 1048576, SEEK_SET) /* 1 megabyte */`
 - `write(fd, "x", 1)`
- What if we add
 - `lseek(fd, 5242880, SEEK_SET) /* 5 megabytes */`
 - `write(fd, "x", 1)`

Solution?

4K blocks, 4 byte block numbers => 1024 block numbers in indirect blocks (10 bit index)

Block # range	location
0 --- 11	Direct blocks
12 --- 1035 (11 + 1024)	Single-indirect blocks
1036 --- 1049611 (1035 + 1024 * 1024)	Double-indirect blocks
1049612 --- ????	Triple-indirect blocks

File (not to scale)

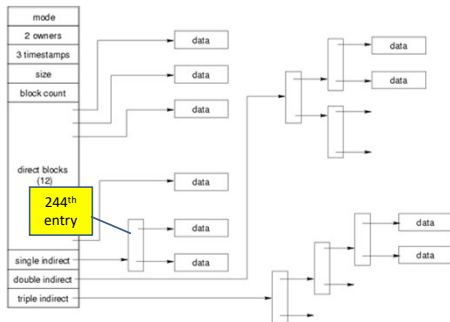

Solution

Address = 1048576 ==>
 block number = 1048576 / 4096 = 256

Single indirect offset = 256 - 12 = 244

Block # range	location
0 --- 11	Direct blocks
12 --- 1035	Single-indirect blocks
1036 --- 1049611	Double-indirect blocks
1049612 --- ????	Triple-indirect blocks

Where is the block number in this tree?

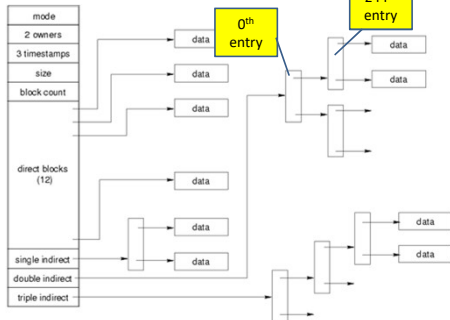

Solution

Address = 5242880 ==>
 Block number = 5242880/4096
 = 1280
 Double indirect offset (20-bit)
 = 1280 - 1036
 = 244
 Top 10 bits = 0
 Lower 10 bits = 244

Block # range	location
0 --- 11	Direct blocks
12 --- 1035	Single-indirect blocks
1036 --- 1049611	Double-indirect blocks
1049612 --- ????	Triple-indirect blocks

Where is the block number in this tree?

Some Best and Worst Case Access Patterns

Assume Inode already in memory

- To read 1 byte
 - Best:
 - 1 access via direct block
 - Worst:
 - 4 accesses via the triple indirect block
- To write 1 byte
 - Best:
 - 1 write via direct block (with no previous content)
 - Worst:
 - 4 reads (to get previous contents of block via triple indirect) + 1 write (to write modified block back)

Worst Case Access Patterns with Unallocated Indirect Blocks

- Worst to write 1 byte
 - 4 writes (3 indirect blocks; 1 data)
 - 1 read, 4 writes (read-write 1 indirect, write 2; write 1 data)
 - 2 reads, 3 writes (read 1 indirect, read-write 1 indirect, write 1; write 1 data)
 - 3 reads, 2 writes (read 2, read-write 1; write 1 data)
- Worst to read 1 byte
 - If reading writes a zero-filled block on disk
 - Worst case is same as write 1 byte
 - If not, worst-case depends on how deep is the current indirect block tree.

Inode Summary

- The inode (and indirect blocks) contains the on-disk metadata associated with a file
 - Contains mode, owner, and other bookkeeping
 - Efficient random and sequential access via *indexed allocation*
 - Small files (the majority of files) require only a single access
 - Larger files require progressively more disk accesses for random access
 - Sequential access is still efficient
 - Can support really large files via increasing levels of indirection

Where/How are Inodes Stored

- System V Disk Layout (s5fs)
 - Boot Block
 - contain code to bootstrap the OS
 - Super Block
 - Contains attributes of the file system itself
 - e.g. size, number of inodes, start block of inode array, start of data block area, free inode list, free data block list
 - Inode Array
 - Data blocks

31

Some problems with s5fs

- Inodes at start of disk; data blocks end
 - Long seek times
 - Must read inode before reading data blocks
- Only one superblock
 - Corrupt the superblock and entire file system is lost
- Block allocation was suboptimal
 - Consecutive free block list created at FS format time
 - Allocation and de-allocation eventually randomises the list resulting in random allocation
- Inode free list also randomised over time
 - Directory listing resulted in random inode access patterns

32

Berkeley Fast Filesystem (FFS)

- Historically followed s5fs
- Addressed many limitations with s5fs
- ext2fs mostly similar

33

Layout of an Ext2 FS

- Partition:
 - Reserved boot block,
 - Collection of equally sized *block groups*
 - All block groups have the same structure

34

Layout of a Block Group

- Replicated** super block
 - For e2fsck
- Group descriptors
- Bitmaps identify used inodes/blocks
- All block groups have the same number of data blocks
- Advantages of this structure:
 - Replication simplifies recovery
 - Proximity of inode tables and data blocks (reduces seek time)

35

Superblocks

- Size of the file system, block size and similar parameters
- Overall free inode and block counters
- Data indicating whether file system check is needed:
 - Uncleanly unmounted
 - Inconsistency
 - Certain number of mounts since last check
 - Certain time expired since last check
- Replicated to provide redundancy to aid recoverability**

36

Group Descriptors

- Location of the bitmaps
- Counter for free blocks and inodes in this group
- Number of directories in the group

Performance considerations

- EXT2 optimisations
 - Block groups cluster related inodes and data blocks
- Pre-allocation of blocks on write (up to 8 blocks)
- 8 bits in bit tables
- Better contiguity when there are concurrent writes
- Aim to store files within a directory in the same group

Thus far...

- Inodes representing files laid out on disk.
- Inodes are referred to by number!!!
- How do users name files? By number?

Ext2fs Directories

inode	rec_len	name_len	type	name...
-------	---------	----------	------	---------

- Directories are files of a special type
 - Consider it a file of special format, managed by the kernel, that uses most of the same machinery to implement it
 - Inodes, etc...
- Directories translate names to inode numbers
- Directory entries are of variable length
- Entries can be deleted in place
 - inode = 0
 - Add to length of previous entry

Ext2fs Directories

- "f1" = inode 7
- "file2" = inode 43
- "f3" = inode 85

Inode No	Rec Length	Name Length	Name
7	12	2	'f' '1' '0' '0'
43	16	5	'f' 'i' 'l' 'e' '2'
85	12	2	'f' '3' '0' '0'
0			

Hard links

- Note that inodes can have more than one name
- Called a *Hard Link*
- Inode (file) 7 has three names
- "f1" = inode 7
- "file2" = inode 7
- "f3" = inode 7

Inode No	Rec Length	Name Length	Name
7	12	2	'f' '1' '0' '0'
7	16	5	'f' 'i' 'l' 'e' '2'
7	12	2	'f' '3' '0' '0'
0

triple indirect

- We can have many names for the same inode.
- When we delete a file by name, i.e. remove the directory entry (link), how does the file system know when to delete the underlying inode?
 - Keep a *reference count* in the inode
 - Adding a name (directory entry) increments the count
 - Removing a name decrements the count
- If the reference count == 0, then we have no names for the inode (it is unreachable), we can delete the inode (underlying file or directory)

THE UNIVERSITY OF NEW SOUTH WALES 43

Hard links

(a) Situation prior to linking
 (b) After the link is created
 (c) After the original owner removes the file

THE UNIVERSITY OF NEW SOUTH WALES

Symbolic links

- A symbolic link is a file that contains a reference to another file or directory
 - Has its own inode and data block, which contains a path to the target file
 - Marked by a special file attribute
 - Transparent for some operations
 - Can point across FS boundaries

THE UNIVERSITY OF NEW SOUTH WALES

Ext2fs Directories

• Deleting a filename
 –rm file2

7	Inode No
12	Rec Length
2	Name Length
'f' '1' '0' '0'	Name
7	
16	
5	
'f' '1' '1' 'e'	
'2' '0' '0' '0'	
7	
12	
2	
'f' '3' '0' '0'	
0	

THE UNIVERSITY OF NEW SOUTH WALES 46

Ext2fs Directories

• Deleting a filename
 –rm file2

• Adjust the record length to skip to next valid entry

7	Inode No
32	Rec Length
2	Name Length
'f' '1' '0' '0'	Name
7	
12	
2	
'f' '3' '0' '0'	
0	

THE UNIVERSITY OF NEW SOUTH WALES 47

FS reliability

- Disk writes are buffered in RAM
 - OS crash or power outage ==> lost data
 - Commit writes to disk periodically (e.g., every 30 sec)
 - Use the sync command to force a FS flush
- FS operations are non-atomic
 - Incomplete transaction can leave the FS in an inconsistent state

THE UNIVERSITY OF NEW SOUTH WALES

FS reliability

dir entries

i-nodes

data blocks

- Example: deleting a file
 1. Remove the directory entry
 2. Mark the i-node as free
 3. Mark disk blocks as free

FS reliability

dir entries

i-nodes

data blocks

- Example: deleting a file
 1. Remove the directory entry --> crash
 2. Mark the i-node as free
 3. Mark disk blocks as free

The i-node and data blocks are lost

FS reliability

dir entries

i-nodes

data blocks

- Example: deleting a file
 1. Mark the i-node as free --> crash
 2. Remove the directory entry
 3. Mark disk blocks as free

The dir entry points to the wrong file

FS reliability

dir entries

i-nodes

data blocks

- Example: deleting a file
 1. Mark disk blocks as free --> crash
 2. Remove the directory entry
 3. Mark the i-node as free

The file randomly shares disk blocks with other files

FS reliability

- e2fsck
 - Scans the disk after an unclean shutdown and attempts to restore FS invariants
- Journaling file systems
 - Keep a journal of FS updates
 - Before performing an atomic update sequence, write it to the journal
 - Replay the last journal entries upon an unclean shutdown
 - Example: ext3fs
