Chapter 6

Deadlocks

6.1. Resources
6.2. Introduction to deadlocks
6.3. The ostrich algorithm
6.4. Deadlock detection and recovery
6.5. Deadlock avoidance
6.6. Deadlock prevention
6.7. Other issues

Learning Outcomes

• Understand what deadlock is and how it can occur when giving mutually exclusive access to multiple resources.
• Understand several approaches to mitigating the issue of deadlock in operating systems.
  * Including deadlock prevention, detection and recovery, and deadlock avoidance.

Resources

• Examples of computer resources
  * printers
  * tape drives
  * Tables in a database
• Processes need access to resources in reasonable order
• Preemptable resources
  * can be taken away from a process with no ill effects
• Nonpreemptable resources
  * will cause the process to fail if taken away

Resources & Deadlocks

• Suppose a process holds resource A and requests resource B
  * at same time another process holds B and requests A
  * both are blocked and remain so - Deadlocked
• Deadlocks occur when ...
  * processes are granted exclusive access to devices, locks, tables, etc..
  * we refer to these entities generally as resources

Resource Access

• Sequence of events required to use a resource
  1. request the resource
  2. use the resource
  3. release the resource
• Must wait if request is denied
  * requesting process may be blocked
  * may fail with error code

Two example resource usage patterns

```c
semaphore res_1, res_2;
void proc_A() {
  down(&area_1);
  down(&area_2);
  use_both_res();
  up(&area_2);
  up(&area_1);
}
void proc_B() {
  down(&area_1);
  down(&area_2);
  use_both_res();
  up(&area_2);
  up(&area_1);
}
```

```c
semaphore res_1, res_2;
void proc_A() {
  down(&area_1);
  down(&area_2);
  use_both_res();
  up(&area_2);
  up(&area_1);
}
void proc_B() {
  down(&area_2);
  down(&area_1);
  use_both_res();
  up(&area_2);
  up(&area_1);
}
```
Introduction to Deadlocks

• Formal definition: 
  A set of processes is deadlocked if each process in the set is waiting for an event that only another process in the set can cause
• Usually the event is release of a currently held resource
• None of the processes can ...
  • run
  • release resources
  • be awakened

Four Conditions for Deadlock

1. Mutual exclusion condition
   - each resource assigned to 1 process or is available
2. Hold and wait condition
   - process holding resources can request additional
3. No preemption condition
   - previously granted resources cannot be forcibly taken away
4. Circular wait condition
   • must be a circular chain of 2 or more processes
   • each is waiting for resource held by next member of the chain

Deadlock Modeling

• Modeled with directed graphs

Deadlock Modeling

1. A requests R
2. C requests T
3. A requests S
4. A requests R
5. A releases R
6. no deadlock

How deadlock can be avoided

1. Prevention
   • negating one of the four necessary conditions
2. Detection and recovery
3. Dynamic avoidance
   • careful resource allocation

How deadlock occurs
Approach 1: The Ostrich Algorithm

• Pretend there is no problem
• Reasonable if
  • deadlocks occur very rarely
  • cost of prevention is high
    • Example of “cost”, only one process runs at a time
• UNIX and Windows takes this approach for some of the more complex resource relationships to manage
• It’s a trade off between
  • Convenience (engineering approach)
  • Correctness (mathematical approach)

Approach 2: Deadlock Prevention

• Resource allocation rules prevent deadlock by prevent one of the four conditions required for deadlock from occurring
  • Mutual exclusion
  • Hold and wait
  • No preemption
  • Circular Wait

Approach 2
Deadlock Prevention
Attacking the Mutual Exclusion Condition

• Not feasible in general
  • Some devices/resource are intrinsically not shareable.

Attacking the Hold and Wait Condition

• Require processes to request resources before starting
  • a process never has to wait for what it needs

• Issues
  • may not know required resources at start of run
  • not always possible
  • also ties up resources other processes could be using

• Variations:
  • process must give up all resources if it would block holding a resource
  • then request all immediately needed
  • prone to livelock

Livelock

• Livelocked processes are not blocked, change state regularly, but never make progress.
• Example: Two people passing each other in a corridor that attempt to step out of each other’s way in the same direction, indefinitely.
  • Both are actively changing state
  • Both never pass each other

Deadlock Example

/* PROCESS 0 */
flag[0] = true;
while (flag[1]) /* do nothing */;
while (flag[0]) /* do nothing */;
/* critical section*/;
flag[0] = false;

/* PROCESS 1 */
flag[1] = true;
while (flag[1]) /* do nothing */;
while (flag[0]) /* do nothing */;
/* critical section*/;
flag[1] = false;
Livelock Example

/* PROCESS 0 */
flag[0] = true;
while (flag[1]){
    flag[0] = false;
    /* delay */;
    flag[0] = true;
}
/* critical section */;
flag[0] = false;

/* PROCESS 1 */
flag[1] = true;
while (flag[0]) {
    flag[1] = false;
    /* delay */;
    flag[1] = true;
}
/* critical section */;
flag[1] = false;

Attacking the No Preemption Condition

• This is not a viable option
• Consider a process given the printer
  • halfway through its job
  • now forcibly take away printer
  • !!!?

Attacking the Circular Wait Condition

• Numerically ordered resources

1. Imagesetter
2. Scanner
3. Plotter
4. Tape drive
5. CD Rom drive

(a) (b)

• Resources ordering is a common technique in practice!!!!!

Example

1 2 3 4
A B

Summary of approaches to deadlock prevention

Condition
• Mutual Exclusion
• Hold and Wait
• No Preemption
• Circular Wait

Approach
• Not feasible
• Request resources initially
• Take resources away
• Order resources
Approach 3: Detection and Recovery

• Need a method to determine if a system is deadlocked.
• Assuming deadlocked is detected, we need a method of recovery to restore progress to the system.

What about resources with multiple units?

• Examples
  • KBs of memory to execute
  • DVD drives to duplicate a disk
  • Blocks on disk to store files

• We need an approach for dealing with resources that consist of more than a single unit.

Note the following invariant

\[ \sum_{i=1}^{n} C_{ij} + A_j = E_j \]
Detection Algorithm

1. Look for an unmarked process $P_i$, for which the $i$-th row of $R$ is less than or equal to $A$
2. If found, add the $i$-th row of $C$ to $A$, and mark $P_i$. Go to step 1
3. If no such process exists, terminate.
   Remaining processes are deadlocked

Example Deadlock Detection

\[ E = \begin{pmatrix} 4 & 2 & 3 & 1 \end{pmatrix} \quad A = \begin{pmatrix} 2 & 1 & 0 & 0 \end{pmatrix} \]
\[ C = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 2 & 0 & 0 & 1 \\ 0 & 1 & 2 & 0 \end{pmatrix} \]
\[ R = \begin{pmatrix} 2 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 \\ 2 & 1 & 0 & 0 \end{pmatrix} \]
Example Deadlock Detection

\[ E = (4 \quad 2 \quad 3 \quad 1) \quad A = (4 \quad 2 \quad 2 \quad 1) \]

\[ C = \begin{pmatrix} 0 & 1 & 0 \\ 2 & 0 & 0 \end{pmatrix} \quad R = \begin{pmatrix} 2 & 0 & 0 \end{pmatrix} \]

37

Example Deadlock Detection

\[ E = (4 \quad 2 \quad 3 \quad 1) \quad A = (4 \quad 2 \quad 2 \quad 1) \]

\[ C = \begin{pmatrix} 0 & 1 & 0 \\ 2 & 0 & 0 \end{pmatrix} \quad R = \begin{pmatrix} 2 & 0 & 0 \end{pmatrix} \]

38

Example Deadlock Detection

\[ E = (4 \quad 2 \quad 3 \quad 1) \quad A = (4 \quad 2 \quad 3 \quad 1) \]

\[ C = \begin{pmatrix} 0 & 1 & 0 \\ 2 & 0 & 0 \end{pmatrix} \quad R = \begin{pmatrix} 2 & 0 & 0 \end{pmatrix} \]

39

Example Deadlock Detection

\[ E = (4 \quad 2 \quad 3 \quad 1) \quad A = (4 \quad 2 \quad 3 \quad 1) \]

\[ C = \begin{pmatrix} 0 & 1 & 0 \\ 2 & 0 & 0 \end{pmatrix} \quad R = \begin{pmatrix} 2 & 0 & 0 \end{pmatrix} \]

40

Example 2: Deadlock Detection

\[ E = (4 \quad 2 \quad 3 \quad 1) \quad A = (2 \quad 1 \quad 0 \quad 0) \]

\[ C = \begin{pmatrix} 0 & 1 & 0 \\ 2 & 0 & 0 \end{pmatrix} \quad R = \begin{pmatrix} 2 & 0 & 0 \end{pmatrix} \]

41

Recovery from Deadlock

- Algorithm terminates with no unmarked processes
  - We have no deadlock

42

Example 2: Deadlock Detection

- Suppose, \( P3 \) needs a CD-ROM as well as 2 Tapes and a Plotter

\[ E = (4 \quad 2 \quad 3 \quad 1) \quad A = (2 \quad 1 \quad 0 \quad 0) \]

\[ C = \begin{pmatrix} 0 & 1 & 0 \\ 2 & 0 & 0 \end{pmatrix} \quad R = \begin{pmatrix} 2 & 0 & 0 \end{pmatrix} \]

42

Recovery from Deadlock

- Recovery through preemption
  - Take a resource from some other process
  - Depends on nature of the resource

- Recovery through rollback
  - Checkpoint a process periodically
  - Use this saved state
  - Restart the process if it is found deadlocked
  - No guarantee is won’t deadlock again

42
Recovery from Deadlock

- Recovery through killing processes
  - crudest but simplest way to break a deadlock
  - kill one of the processes in the deadlock cycle
  - the other processes get its resources
  - choose process that can be rerun from the beginning

Approach 4
Deadlock Avoidance

- Instead of detecting deadlock, can we simply avoid it?
  - YES, but only if enough information is available in advance.
  - Maximum number of each resource required

Deadlock Avoidance
Resource Trajectories

Two process resource trajectories

Safe and Unsafe States

- A state is safe if
  - The system is not deadlocked
  - There exists a scheduling order that results in every process running to completion, even if they all request their maximum resources immediately

Safe and Unsafe States

Note: We have 10 units of the resource

Demonstration that the state in (a) is safe
Safe and Unsafe States

A requests one extra unit resulting in (b)

<table>
<thead>
<tr>
<th>Has</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>4</td>
</tr>
<tr>
<td>B</td>
<td>2</td>
</tr>
<tr>
<td>C</td>
<td>7</td>
</tr>
</tbody>
</table>

(b) Free: 2

Demonstration that the state in b is not safe

Bankers Algorithm

- Modelled on a Banker with Customers
  - The banker has a limited amount of money to loan customers
  - Each customer can borrow money up to their credit limit
  - Maximum number of resources required
- Basic Idea
  - Keep the bank in a safe state
    - So all customers are happy even if they all request to borrow up to their credit limit at the same time.
  - Customers wishing to borrow such that the bank would enter an unsafe state must wait until somebody else repays their loan such that the transaction becomes safe.

The Banker’s Algorithm for a Single Resource

<table>
<thead>
<tr>
<th>Has</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>6</td>
</tr>
<tr>
<td>B</td>
<td>5</td>
</tr>
<tr>
<td>C</td>
<td>4</td>
</tr>
<tr>
<td>D</td>
<td>7</td>
</tr>
</tbody>
</table>

(a) Free: 10

Should we grant B one more?

Banker’s Algorithm for Multiple Resources

<table>
<thead>
<tr>
<th>Process</th>
<th>Request</th>
<th>Available</th>
<th>Resources assigned</th>
<th>Resources still needed</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0</td>
<td>1 1 0</td>
<td>A 0 1 1 0 0</td>
<td></td>
</tr>
<tr>
<td>B</td>
<td>1 1 0</td>
<td>B 0 1 1 2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>0</td>
<td>C 3 1 0 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>D</td>
<td>0 1 0</td>
<td>D 0 0 1 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>E</td>
<td>0 0 0</td>
<td>E 2 1 1 0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example of banker’s algorithm with multiple resources

System should start in safe state!

Banker’s Algorithm for Multiple Resources

<table>
<thead>
<tr>
<th>Process</th>
<th>Request</th>
<th>Available</th>
<th>Resources assigned</th>
<th>Resources still needed</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>3 0 1 1</td>
<td>A 1 1 0 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B</td>
<td>0 1 0 0</td>
<td>B 0 1 1 2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>1 1 0 0</td>
<td>C 3 1 0 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>D</td>
<td>1 1 0 1</td>
<td>D 0 0 1 0</td>
<td></td>
<td></td>
</tr>
<tr>
<td>E</td>
<td>0 0 0 0</td>
<td>E 2 1 1 0</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example of banker’s algorithm with multiple resources

Should we allow a request by B 1 scanner to succeed?
### Banker’s Algorithm for Multiple Resources

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Fonts</td>
<td>3</td>
<td>0</td>
<td>1</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>Printers</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>Scanners</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

Example of banker’s algorithm with multiple resources

Should we allow a request by B and E for 1 scanner to succeed?

Bankers Algorithm is not commonly used in practice

- It is difficult (sometimes impossible) to know in advance
  - the resources a process will require
  - the number of processes in a dynamic system

### Starvation

- A process never receives the resource it is waiting for, despite the resource (repeatedly) becoming free, the resource is always allocated to another waiting process.

  - Example: An algorithm to allocate a resource may be to give the resource to the shortest job first
  - Works great for multiple short jobs in a system
  - May cause a long job to wait indefinitely, even though not blocked.

- One solution:
  - First-come, first-serve policy
