Variables

- Variables are used to store a value.
- The value a variable holds may change over its lifetime.
- At any point in time a variable stores one value (except quantum computers!)
- C variables have a type

We’ll only use 2 types of variable for the next few weeks:

- **int** for integer values, e.g.: 42, -1
- **double** for decimal numbers 3.14159, 2.71828
• typically 4 bytes used to store an `int` variable
• 4 bytes $\rightarrow$ 32 bits $\rightarrow$ $2^{32}$ possible values (bit patterns)
• only $2^{32}$ integers can be represented - which ones?
• $-2^{31}$ to $2^{31} - 1$
  i.e. -2,147,483,648 to +2,147,483,647
• Why are limits asymmetric?
• zero needs a pattern (all zeros)
• can print bit values see:
  https://cgi.cse.unsw.edu.au/~cs1511cgi/lec/C_basics/code/print_bits_of_int.c
• More later and in COMP1521
Integer Overflow/Underflow

- storing a value in an `int` outside the range that can be represented is illegal
- unexpected behaviour from most C implementations e.g. the sum of 2 large positive integers is negative
- may cause programs to halt, or not to terminate
- can creates security holes
- bits used for `int` can be different on other platforms
- C on tiny embedded CPU in washing machine may use 16 bits $-2^{15}$ to $2^{15} - 1$ i.e. -32,768 to +32767
- we’ll show later how to handle this, for now assume 32 bit `ints`
- also arbitrary precision libraries available for C manipulate integers of any size (memory permitting)
Real Representation

- commonly 8 bytes used to store a `double` variable
- 8 bytes $\rightarrow$ 64 bits $\rightarrow$ $2^{64}$ possible values (bit patterns)
- 64-bits gives huge number of patterns but infinite number of reals
- reals in (absolute) range $10^{-308}$ to $10^{308}$ can be approximated
- approximation errors can accumulate
- More later and in COMP1521
Variables

- **Declare** The first time a variable is mentioned, we need to specify its type.
- **Initialise** Before using a variable we need to assign it a value.

```c
// Declare
int answer;
// Initialise
answer = 42;
// Use
printf("%d", num);
```
Variable Names (and other Identifiers)

• Variable names can made up of letters, digits and underscores
• Use a lower case letter to start your variable names
• Beware variable names are case sensitive,
  e.g. hello and hEllo are different names)
• Beware certain words can’t be used as variable names:
  e.g.: if, while, return, int, double
• These keywords have special meanings in C programs.
• You’ll learn what many of them are as we go on.
Output using printf()

- No variables:

```c
printf("Hello World\n");
```

- A single variable:

```c
int num = 5;
printf("num is %d\n", num);
```

- More than one variable:

```c
int j = 5;
int k = 17;
printf("j is %d and k is %d\n", j, k);
```
Using values in printf()

- Use **%d** to print an **int** (integer) value

```c
int answer;
answer = 42;
printf("The answer is %d\n", answer);
```

- Use **%lf** or **%g** to print a **double** (floating point) value

```c
double pi;
pi = 3.14159265359;
printf("pi is %lf\n", pi);
```
Input using scanf()

scanf uses a format string like printf.

- Use %d to read an int (integer) value

```c
int answer;
printf("Enter the answer: ");
scanf("%d", &answer);
```

- Use %lf to read a double (floating point) value

```c
double e;
printf("Enter e: ");
scanf("%lf", &e);
```

- Use only "%d" and "%lf" format strings with scanf
- read only 1 value at a time with scanf
- scanf can be used in other ways - don’t do it
- we’ll show you better ways to do other input
Numbers and Types

• Numbers in programs have types.
• Numbers with a decimal point are type `double`, e.g. 3.14159 -34.56 42.0
• C also lets write numbers in scientific notation:
  2.4e5 \rightarrow 2.4 \times 10^5 \rightarrow 240000.0
  Numbers in scientific notation are also type `double`
• Numbers without decimal point or exponent are type `int`, e.g. 42 0 -24
• Numbers in programs are often called constants
  (unlike variables they don’t change)
• It can be useful to give constants (numbers) a name.
• It often makes your program more readable.
• It can make your program easier to update particularly if the constant appears in many places.
• One method is `#define` statement e.g.
  `#define SPEED_OF_LIGHT 299792458.0`
• `#define` statements go at the top of your program after `#include` statements
• `#define` names should be all capital letters + underscore
C supports the usual maths operations: $+ - * /$

Precedence is as you would expect from high school, e.g.:
$a + b * c + d / e \implies a + (b * c) + (d / e)$

Associativity (grouping) is as you would expect from high school, e.g.:
$a - b - c - d \implies ((a - b) - c) - d$

Use brackets if in doubt about order arithmetic will be evaluated.

Beware division may not do what you expect.
Division in C

- C division does what you expect if either operand is a `double`. If either operand is a `double` the result is a `double`.
  \[ 2.6/2 \Rightarrow 1.3 \text{ (not 2!)} \]

- C division may not do what you expect if both arguments are integers.
  - The result of dividing 2 integers in C is an integer.
  - The fractional part is discarded (not rounded!).
    \[ 5/3 \Rightarrow 1 \text{ (not 2!)} \]

- C also has the `%` operator (integers only). Computes the modulo (remainder after division).
  \[ 14 \% 3 \Rightarrow 2 \]
Mathematical functions

- Mathematical functions not part of standard library
  Essentially because tiny CPUs may not support them
- A library of mathematical functions is available including:
  `sqrt()`, `sin()`, `cos()`, `log()`, `exp()`
  Above functions take a **double** as argument and return a **double**
- Functions covered fully later in course
- Extra include line needed at top of program:
  ```
  #include <math.h>
  ```
  (explained later in course)
- `dcc` includes maths library by default
  most compilers need extra option:
  `gcc` needs `-lm` e.g.:
  ```
  gcc -o heron heron.c -lm
  ```
Other functions - printf & scanf

- printf & scanf are functions
- scanf returns a value (returns number of items read)
- Use this value to determine if scanf successfully read number.
- scanf could fail e.g. if the user enters letters
- OK for now to assume scanf succeeds
- Good programmers always check
Linux Command: `cp`

- Linux Command `cp`: copies files and directories.
- `cp sourceFile destination`
- If the destination is an existing file, the file is overwritten.
- If the destination is an existing directory, the file is copied into the directory.
- To copy a directory use `cp -r sourceDir destination`
Linux Command: `mv`

- Linux Command **mv** moves or renames a file.
- `mv source destination`
- If the destination is an existing file, the file is overwritten
- if the destination is an existing directory
  the file is moved into the directory.
Linux Command: `rm`

- Linux Command `rm` removes a file.
- Usually no undo or recycle bin - be careful & have backups
- `rm filename`
- `rm -r directoryName`
  - This will delete a whole directory.
  - Be extra careful with this command
