The char Type

- The C type `char` stores small integers.
- It is 8 bits (almost always).
- `char` guaranteed able to represent integers 0 .. +127.
- `char` mostly used to store ASCII character codes.
- Don’t use `char` for individual variables, only arrays
- Only use `char` for characters.
- Even if a numeric variable is only use for the values 0..9, use the type `int` for the variable.

ASCII Encoding

- ASCII (American Standard Code for Information Interchange)
- Specifies mapping of 128 characters to integers 0..127.
- The characters encoded include:
  - upper and lower case English letters: A-Z and a-z
  - digits: 0-9
  - common punctuation symbols
  - special non-printing characters: e.g. newline and space.
- You don’t have to memorize ASCII codes
  Single quotes give you the ASCII code for a character:
  ```c
  printf("%d", 'a'); // prints 97
  printf("%d", 'A'); // prints 65
  printf("%d", '0'); // prints 48
  printf("%d", ' ' + '\n'); // prints 42 (32 + 10)
  ```
- Don’t put ASCII codes in your program - use single quotes instead.

Manipulating Characters

The ASCII codes for the digits, the upper case letters and lower case letters are contiguous.
This allows some simple programming patterns:

```c
// check for lowercase
if (c >= 'a' && c <= 'z') {
  ...
}
```
```
// check is a digit
if (c >= '0' && c <= '9') {
  // convert ASCII code to corresponding integer
  numeric_value = c - '0';
}
```

Reading a Character - getchar

C provides library functions for reading and writing characters
- `getchar` reads a byte from standard input.
- `getchar` returns an int
- `getchar` returns a special value (EOF usually -1) if it can not read a byte.
- Otherwise `getchar` returns an integer (0..255) inclusive.
- If standard input is a terminal or text file this likely be an ASCII code.
- Beware input often buffered until entire line can be read.

```c
int c;
printf("Please enter a character: ");
c = getchar();
printf("The ASCII code of the character is %d\n", c);
```
Reading a Character - getchar

Consider the following code:

```c
int c1, c2;

printf("Please enter first character:\n");
c1 = getchar();
printf("Please enter second character:\n");
c2 = getchar();
printf("First %d\nSecond: %d\n", c1, c2);
```

The newline character from pressing *Enter* will be the second character read.

How can we fix the program?

```c
int c1, c2;

printf("Please enter first character:\n");
c1 = getchar();
getchar(); // reads and discards a character
printf("Please enter second character:\n");
c2 = getchar();
printf("First: %c\nSecond: %c\n", c1, c2);
```

End of Input

- Input functions such as `scanf` or `getchar` can fail because no input is available, e.g., if input is coming from a file and the end of the file is reached.
- On UNIX-like systems (Linux/OSX) typing **Ctrl + D** signals to the operating system no more input from the terminal.
- Windows has no equivalent - some Windows programs interpret **Ctrl + Z** similarly.
- `getchar` returns a special value to indicate there is no input was available.
- This non-ASCII value is *#*defined as `EOF` in `stdio.h`.
- On most systems `EOF == -1`. Note `getchar` otherwise returns (0.255) or (0..127) if input is ASCII
- There is no end-of-file character on modern operating systems.

Reading Characters to End of Input

Programming pattern for reading characters to the end of input:

```c
int ch;

ch = getchar();
while (ch != EOF) {
    printf("%c' read, ASCII code is %d\n", ch, ch);
    ch = getchar();
}
```

For comparison the programming pattern for reading integers to end of input:

```c
int num;
// scanf returns the number of items read
while (scanf("%d", &num) == 1) {
    printf("you entered the number: %d\n", num);
}
Strings

- A string in computer science is a sequence of characters.
- In C strings are an array of `char` containing ASCII codes.
- These array of char have an extra element containing a 0.
- The extra 0 can also be written `\0` and may be called a null character or null-terminator.
- This is convenient because programs don’t have to track the length of the string.

Useful C Library Functions for Characters

The C library includes some useful functions which operate on characters. Several of the more useful listed below.

```c
#include <ctype.h>

int toupper(int c); // convert c to upper case
int tolower(int c); // convert c to lower case
int isalpha(int c); // test if c is a letter
int isdigit(int c); // test if c is a digit
int islower(int c); // test if c is lower case letter
int isupper(int c); // test if c is upper case letter
```

fgets - Read a Line

- `fgets(array, array_size, stream)` reads a line of text
  1. `array` - char array in which to store the line
  2. `array_size` - the size of the array
  3. `stream` - where to read the line from, e.g. stdin
- `fgets` will not store more than `array_size` characters in array
- Never use similar C function `gets` which can overflow the array and major source of security exploits
- `fgets` always stores a `\0` terminating character in the array.
- `fgets` stores a `\n` in the array if it reads entire line often need to overwrite this newline character:

```c
int i = strlen(line);
if (i > 0 && line[i - 1] == "\n") {
    line[i - 1] = '\0';
}
```
## Reading an Entire Input Line

You might use `fgets` as follows:

```c
#define MAX_LINE_LENGTH 1024
...
char line[MAX_LINE_LENGTH];
printf("Enter a line: ");
// fgets returns NULL if it can't read any characters
if (fgets(line, MAX_LINE_LENGTH, stdin) != NULL { 
  fputs(line, stdout);
  // or
  printf("%s", line); // same as fputs
}
```

## Reading Lines to End of Input

Programming pattern for reading lines to end of input:

```c
// fgets returns NULL if it can't read any characters
while (fgets(line, MAX_LINE_LENGTH, stdin) != NULL) {
  printf("you entered the line: %s", line);
}
```

## string.h

```c
#include <string.h>

// string length (not including '\0')
int strlen(char *s);

// string copy
char *strcpy(char *dest, char *src);
char *strncpy(char *dest, char *src, int n);

// string concatenation/append
char *strcat(char *dest, char *src);
char *strncat(char *dest, char *src, int n);
```

## string.h

```c
#include <string.h>

// string compare
int strcmp(char *s1, char *s2);
int strncmp(char *s1, char *s2, int n);
int strcasecmp(char *s1, char *s2);
int strncasecmp(char *s1, char *s2, int n);

// character search
char *strchr(char *s, int c);
char *strrchr(char *s, int c);
```
Command-line Arguments

Command-line arguments are 0 more strings specified when a program is run. If you run this command in a terminal:

```bash
$ gcc count.c -o count
```
dcc will be given 3 command-line arguments: "count.c" "-o" "count"

bf main needs different prototype if you want to access command-line arguments

```c
int main(int argc, char *argv[]) { ...
```

Converting Command-line Arguments

stdlib.h defines useful functions to convert strings.

```c
#include <stdio.h>
#include <stdlib.h>
int main(int argc, char *argv[]) {
    int i, sum = 0;
    i = 1;
    while (i < argc) {
        sum = sum + atoi(argv[i]);
        i = i + 1;
    }
    printf("sum of command-line arguments=%d\n", sum);
}
```

Accessing Command-line Arguments

```c
argc stores the number of command-line arguments + 1
argc == 1 if no command-line arguments
argv stores program name + command-line arguments
argv[0] always contains the program name
```

```c
#include <stdio.h>
int main(int argc, char *argv[]) {
    int i = 1;
    printf("My name is %s\n", argv[i]);
    while (i < argc) {
        printf("Argument %d is: %s\n", i, argv[i]);
        i = i + 1;
    }
}
```
