Floating Point Numbers

- C has three floating point types
  - `float` ... typically 32-bit (lower precision, narrower range)
  - `double` ... typically 64-bit (higher precision, wider range)
  - `long double` ... typically 128-bits (but maybe only 80 bits used)
- Floating point constants, e.g.: `3.14159` `1.0e-9` are `double`
- Reminder: division of 2 ints in C yields an int.
  - but division of double and int in C yields a double.

```c
double d = 4/7.0;  // prints in decimal with (default) 6 decimal places
printf("%lf\n", d);  // prints 0.571429
// prints in scientific notation
printf("%le\n", d);  // prints 5.714286e-01
// picks best of decimal and scientific notation
printf("%lg\n", d);  // prints 0.571429
// prints in decimal with 9 decimal places
printf("%.9lf\n", d);  // prints 0.571428571
// prints in decimal with 1 decimal place and field width of 5
printf("%.1lf\n", d);  // prints 0.6
```

Source code for `float_output.c`
Floating Point Numbers

- if we represent floating point numbers with a fixed small number of bits
  - there are only a finite number of bit patterns
  - can only represent a finite subset of reals
- almost all real values will have no exact representation
- value of arithmetic operations may be real with no exactly representation
- we must use closest value which can be exactly represented
- this approximation introduces an error into our calculations
- often, does not matter
- sometimes ... can be disastrous

Fixed Point Representation

- can have fractional numbers in other bases, e.g.: \( 110.101_2 = 6.625_{10} \)
- could represent fractional numbers similarly to integers by assuming decimal point is in **fixed** position
- for example with 32 bits:
  - 16 bits could be used for integer part
  - 16 bits could be used for the fraction
  - equivalent to storing values as integers after multiplying (**scaling**) by \( 2^{16} \)
  - major limitation is only small range of values can be represented
    - minimum \( 2^{-16} \approx 0.000015 \)
    - maximum \( 2^{15} \approx 32768 \)
- usable for some problems, but not ideal
- used on small embedded processors without silicon floating point

---

default_types.c - print characteristics of floating point types

```c
float f;
double d;
long double l;
printf("float %2lu bytes min=%-12g max=%g\n", sizeof f, FLT_MIN, FLT_MAX);
printf("double %2lu bytes min=%-12g max=%g\n", sizeof d, DBL_MIN, DBL_MAX);
printf("long double %2lu bytes min=%-12Lg max=%Lg\n", sizeof l, LDBL_MIN, LDBL_MAX);
```

source code for default_types.c

```bash
$ ./default_types
float 4 bytes min=1.17549e-38 max=3.40282e+38
double 8 bytes min=2.22507e-308 max=1.79769e+308
long double 16 bytes min=3.3621e-4932 max=1.18973e+4932
```
IEEE 754 standard

- C floats almost always IEEE 754 single precision (binary32)
- C double almost always IEEE 754 double precision (binary64)
- C long double might be IEEE 754 (binary128)
- IEEE 754 representation has 3 parts: sign, fraction and exponent
- numbers have form $sign \times fraction \times 2^{exponent}$, where sign is +/-
- $fraction$ always has 1 digit before decimal point (normalized)
  - as a consequence only 1 representation for any value
- $exponent$ is stored as positive number by adding constant value (bias)
- numbers close to zero have higher precision (more accurate)

Floating Point Numbers

Example of normalising the fraction part in binary:
- 1010.1011 is normalized as $1.0101011 \times 2^{11}$
- $1010.1011 = 10 + 11/16 = 10.6875$

$1.0101011 \times 2^{11} = (1 + 43/128) \times 2^3 = 1.3359375 \times 8 = 10.6875$

The normalised fraction part always has 1 before the decimal point.

Example of determining the exponent in binary:
- if exponent is 8-bits, then the bias = $2^8-1 - 1 = 127$
- valid bit patterns for exponent 00000001 .. 11111110
- correspond to $B$ exponent values -126 .. 127

Floating Point Numbers

Internal structure of floating point values

![Floating Point Numbers Diagram](https://www.cse.unsw.edu.au/~cs1521/21T2/COMP1521_21T2%20Floating-Point%20Numbers)
0.15625 is represented in IEEE-754 single-precision by these bits:
00111110000100000000000000000000

infinity.c: exploring infinity

- IEEE 754 has a representation for +/- infinity
- propagates sensibly through calculations

```c
double x = 1.0/0.0;
printf("%lf\n", x); // prints inf
printf("%lf\n", -x); // prints -inf
printf("%lf\n", x - 1); // prints inf
printf("%lf\n", 2 * atan(x)); // prints 3.141593
printf("%d\n", 42 < x); // prints 1 (true)
printf("%d\n", x == INFINITY); // prints 1 (true)
```

source code for infinity.c

---

https://www.cse.unsw.edu.au/~cs1521/21T2/ COMP1521 21T2 — Floating-Point Numbers
C (IEEE-754) has a representation for invalid results:
- NaN (not a number)
- ensures errors propagate sensibly through calculations

```c
double x = 0.0/0.0;
printf("%lf\n", x); // prints nan
printf("%lf\n", x - 1); // prints nan
printf("%d\n", x == x); // prints 0 (false)
printf("%d\n", isnan(x)); // prints 1 (true)
```

source code for nan.c

IEEE-754 Single Precision example: `inf`

```
$ ./explain_float_representation inf
inf is represented in IEEE-754 single-precision by these bits:
01111111000000000000000000000000
sign | exponent | fraction
 0 | 11111111 | 000000000000000000000000
sign bit = 0
sign = +
raw exponent = 11111111 binary
= 255 decimal
number = +inf
```

IEEE-754 Single Precision exploring bit patterns #2

```
$ ./explain_float_representation 01111111110000000000000000000000
sign bit = 0
sign = +
raw exponent = 11111111 binary
= 255 decimal
number = NaN
```

source code for explain_float_representation.c
Consequences of most reals not having exact representations

double a, b;
a = 0.1;
b = 1 - (a + a + a + a + a + a + a + a + a + a);
if (b != 0) {
    // better would be fabs(b) > 0.000001
    printf("1 != 0.1+0.1+0.1+0.1+0.1+0.1+0.1+0.1+0.1+0.1\n");
}
printf("b = %g\n", b); // prints 1.11022e-16

- do not use == and != with floating point values
- instead check if values are close

Consequences of most reals not having exact representations

double x = 0.000000011;
double y = (1 - cos(x)) / (x * x);
// correct answer y = ~0.5
// prints y = 0.917540
printf("y = %lf\n", y);
// division of similar approximate value
// produces large error
// sometimes called catastrophic cancellation
printf("%g\n", 1 - cos(x)); // prints 1.11022e-16
printf("%g\n", x * x); // prints 1.21e-16

Another reason not to use == with floating point values

if (d == d) {
    printf("d == d is true\n");
} else {
    // will be executed if d is a NaN
    printf("d == d is not true\n");
}
if (d == d + 1) {
    // may be executed if d is large
    // because closest possible representation for d + 1
    // is also closest possible representation for d
    printf("d == d + 1 is true\n");
} else {
    printf("d == d + 1 is false\n");
}
Another reason not to use == with floating point values

```sh
$ gcc double_not_always.c -o double_not_always
$ ./double_not_always 42.3
d = 42.3
d == d is true
d == d + 1 is false
$ ./double_not_always 4200000000000000000
d = 4.2e+18
d == d is true
d == d + 1 is true
$ ./double_not_always NaN
d = nan
d == d is not true
d == d + 1 is false

because closest possible representation for d + 1 is also closest possible representation for d
```

Consequences of most reals not having exact representations

```c
double d = 9007199254740992;
// loop never terminates
while (d < 9007199254740999) {
    printf("%lf\n", d); // always prints 9007199254740992.000000
    // 9007199254740993 can not be represented as a double
    // closest double is 9007199254740992.0
    // so 9007199254740992.0 + 1 = 9007199254740992.0
    d = d + 1;
}
```

- 9007199254740993 is $2^{53} + 1$
  - it is smallest integer which can not be represented exactly as a double
- The closest double to 9007199254740993 is 9007199254740992.0
- aside: 9007199254740993 can not be represented by a int32_t
  - it can be represented by int64_t

Exercise: Floating point → Decimal

Convert the following floating point numbers to decimal.

Assume that they are in IEEE 754 single-precision format.

0 10000000 11000000000000000000000
1 01111111 10000000000000000000000
