

COMP1521 23T2 — MIPS Control

<https://www.cse.unsw.edu.au/~cs1521/23T2/>

Jump Instructions

assembler	meaning	bit pattern
j <i>label</i>	pc = pc & 0xF0000000 (X«2)	000010XXXXXXXXXXXXXXXXXXXXXXXXXXXX
jal <i>label</i>	ra = pc + 4; pc = pc & 0xF0000000 (X«2)	000011XXXXXXXXXXXXXXXXXXXXXXXXXXXX
jr <i>r_s</i>	pc = <i>r_s</i>	000000sssss00000000000000001000
jalr <i>r_s</i>	ra = pc + 4; pc = <i>r_s</i>	000000sssss00000000000000001001

- jump instructions **unconditionally** transfer execution to a new location
 - in other word, jump instructions change the pc (program counter)
- for **j label** and **jal label** mipsy calculates correct value for X from location of ****label** in code
- **jal** & **jalr** set \$ra (\$31) to address of the next instruction
 - call to function *f* implemented by **jal f**
 - return can then be implemented with **jr \$ra**
- **jr** & **jalr** can be used with any register
 - used to implement function pointer dereferencing in C, and methods in object-oriented languages

Branch Instructions

b <i>label</i>	pc += I«2	pseudo-instruction
beq <i>r_s, r_t, label</i>	if (<i>r_s</i> == <i>r_t</i>) pc += I«2	000100ssssssttttIIIIIIIIIIIIIIIIIIII
bne <i>r_s, r_t, label</i>	if (<i>r_s</i> != <i>r_t</i>) pc += I«2	000101ssssssttttIIIIIIIIIIIIIIIIIIII
ble <i>r_s, r_t, label</i>	if (<i>r_s</i> <= <i>r_t</i>) pc += I«2	pseudo-instruction
bgt <i>r_s, r_t, label</i>	if (<i>r_s</i> > <i>r_t</i>) pc += I«2	pseudo-instruction
blt <i>r_s, r_t, label</i>	if (<i>r_s</i> < <i>r_t</i>) pc += I«2	pseudo-instruction
bge <i>r_s, r_t, label</i>	if (<i>r_s</i> >= <i>r_t</i>) pc += I«2	pseudo-instruction
blez <i>r_s, label</i>	if (<i>r_s</i> <= 0) pc += I«2	000110sssss00000IIIIIIIIIIIIIIIIIIII
bgtz <i>r_s, label</i>	if (<i>r_s</i> > 0) pc += I«2	000111sssss00000IIIIIIIIIIIIIIIIIIII
bltz <i>r_s, label</i>	if (<i>r_s</i> < 0) pc += I«2	000001sssss00000IIIIIIIIIIIIIIIIIIII
bgez <i>r_s, label</i>	if (<i>r_s</i> >= 0) pc += I«2	000001sssss00001IIIIIIIIIIIIIIIIIIII
bnez <i>r_s, label</i>	if (<i>r_s</i> != 0) pc += I«2	pseudo-instruction
beqz <i>r_s, label</i>	if (<i>r_s</i> == 0) pc += I«2	pseudo-instruction

- branch instruction **conditionally** transfer execution to a new location (except **b** is unconditional)
- mipsy will calculate correct value for I from location of *label* in code
- mipsy allows second operand (*r_t*) to be replaced by a constant (fine to use in COMP1521)

Pseudo-Instructions

```
bge $t1, $t2, label

blt $t1, 42, label

beqz $t3, label

bnez $t4, label

b label
```

Real Instructions

```
slt $at, $t1, $t2
beq $at, $0, label

addi $at, $zero, 42
slt $at, $t1, $at
bne $at, $0, label

beq $t3, $0, label

bne $t4, $0, label

beq $0, $0, label
```

Branch versus Jump

- jump instructions are unconditional
- branch instructions are conditional and can implement if and while
 - except **b label** which has same effect as **j label**
 - you can use either
- **jal** and **jr** instructions provides a simple function call & return implementations
 - no equivalent branch instructions
- branch instruction encode a 16-bit relative offset
 - target (label) must be within -32768..32767 instructions
 - not a problem in COMP1521 - we write small programs
- jump instruction encode a 28-bit value
 - allows jumps to be used for targets (labels) further away

goto in C

The **goto** statement allows transfer of control to any labelled point with a function. For example, this code:

```
for (int i = 1; i <= 10; i++) {
    printf("%d\n", i);
}
```

can be written as:

```
int i = 1;
loop:
    if (i > 10) goto end;
    i++;
    printf("%d", i);
    printf("\n");
    goto loop;
end:
```

C

```
int main(void) {
    for (int i = 1; i <= 10; i++) {
        printf("%d\n", i);
    }
    return 0;
}
```

source code for print10.c

Simplified C

```
int main(void) {
    int i;
    i = 1;
loop:
    if (i > 10) goto end;
    printf("%d", i);
    printf("\n");
    i++;
    goto loop;
end:
    return 0;
}
```

source code for print10.simple.c

Printing First 10 Integers: MIPS

```
# print integers 1..10 one per line
main:                                # int main(void) {
                                     # int i; // in register $t0
    li    $t0, 1                      # i = 1;
loop:                                 # loop:
    bgt   $t0, 10, end                # if (i > 10) goto end;
    move  $a0, $t0                    # printf("%d" i);
    li    $v0, 1
    syscall
    li    $a0, '\n'                   # printf("%c", '\n');
    li    $v0, 11
    syscall
    addi  $t0, $t0, 1                 # i++;
    b     loop                         # goto loop;
end:
    li    $v0, 0                      # return 0
    jr    $ra
```

```

source code for sum_100_squares.s

goto in C

- **goto** statements can result in very difficult to read programs.
- **goto** statements can also result in slower programs.
- In general, use of **goto** is considered **bad** programming style.
- Do not use **goto** without very good reason.
- kernel & embedded programmers sometimes use goto.

Writing correct assembler directly is hard.

Recommended strategy:

- develop a solution in C
- map down to “simplified” C
- translate simplified C statements to MIPS instructions

Simplified C

- does *not* have `while`, compound `if`, complex expressions
- *does* have simple `if`, `goto`, one-operator expressions

Simplified C makes extensive use of

- *labels* ... symbolic name for C statement
- *goto* ... transfer control to labelled statement

Mapping C into MIPS

Things to do:

- allocate variables to registers/memory
- place literals in data segment
- transform C program to:
 - break expression evaluation into steps
 - replace most control structures by `goto`

Conditionals — `if` from C to Simplified C

Standard C

```
if (i < 0) {
    n = n - i;
} else {
    n = n + i;
}
```

Simplified C

```
if (i >= 0) goto else1;
n = n - i;
goto end1;
else1:
    n = n + i;
end1:
```

note: `else` is not a valid label name in C

Simplified C

```

if (i >= 0) goto else1;
n = n - i;
goto end1;
else1:
  n = n + i;
end1:

```

MIPS

```

# assuming i in $t0,
# assuming n in $t1...

bge $t0, 0, else1
sub $t1, $t1, $t0
goto end1
else1:
  add $t1, $t1, $t0
end1:

```

Odd or Even: C to simplified C

C

```

int main(void) {
  int n;
  printf("Enter a number: ");
  scanf("%d", &n);
  if (n % 2 == 0) {
    printf("even\n");
  } else {
    printf("odd\n");
  }
  return 0;
}

```

source code for odd_even.c

Simplified C

```

int main(void) {
  int n;
  printf("Enter a number: ");
  scanf("%d", &n);
  if (n % 2 != 0) goto n_mod_2_ne_0;
  printf("even\n");
  goto epilogue;
n_mod_2_ne_0:
  printf("odd\n");
epilogue:
  return 0;
}

```

source code for odd_even.simple.c

Odd or Even: MIPS

```

```
if (i < 0 && n >= 42) {
    n = n - i;
} else {
    n = n + i;
}
```

Simplified C

```
if (i >= 0) goto else1;
if (n < 42) goto else1;
n = n - i;
goto end1;
else1:
    n = n + i;
end1:
```

<https://www.cse.unsw.edu.au/~cs1521/23T2/>

COMP1521 23T2 — MIPS Control

27 / 34

Simplified C

```

if (i >= 0) goto else1;
if (n < 42) goto else1;
n = n - i;
goto end1;
else1:
  n = n + i;
end1:

```

MIPS

```

# assume i in $t0
# assume n in $t1

bge $t0, 0, else1
blt $t1, 42, else1
sub $t1, $t1, $t0
j end1
else1:
add $t1, $t1, $t0
end1:

```

Conditionals — if and ||: from C to Simplified C

Standard C

```

if (i < 0 || n >= 42) {

    n = n - i;

} else {
    n = n + i;
}

```

Simplified C

```

if (i < 0) goto then1;
if (n >= 42) goto then1;
goto else1;
then1:
  n = n - i;
goto end1;
else1:
  n = n + i;
end1:

```

Conditionals — if and ||: from Simplified C to MIPS

Simplified C

```

if (i < 0) goto then1;
if (n >= 42) goto then1;
goto else1;
then1:
  n = n - i;
goto end1;
else1:
  n = n + i;
end1:

```

MIPS

```

# assume i in $t0
# assume n in $t1

blt $t0, 0, else1
bge $t1, 42, else1
sub $t1, $t1, $t0
j end1
else1:
add $t1, $t1, $t0
end1:

```

The break statement

Sometimes it is useful to exit from the middle of a loop

- `break` allows you to check a condition mid-loop and quit

```
// read up to 100 characters
// stop if the next character is '!'
while (i <= 100) {
    int ch = getchar();
    if (ch == '!') break;
    putchar(ch);
}
```

The continue statement

Sometimes it is useful to go to next iteration and skip rest of loop

- `continue` allows you to go to next iteration from mid-loop

```
// iterate over integers 1..100
// skip every multiple of three
for (i = 1; i <= 100; i++) {
    if (i % 3 == 0) continue;
    printf("%d\n", i);
}
```

continue can simplify loops

::: columns ::: column

```
while (Condition) {
    some_code_1
    if (Condition1) {
        some_code_2
        if (Condition2) {
            some_code_3
        }
    }
}
```

:::: column

```
while (_Condition_) {
    some_code_1
    if (! Condition1) continue;
    some_code_2
    if (! Condition2) continue;
    some_code_3
}
```

C has a different while loop - do/while (post-test).

- loop condition checked at bottom of loop - always executed once
- many programmers do not use it

```
do {  
    printf("%d\n", i);  
    i++;  
} while (i < 10);
```

can be written as:

```
int i = 1;  
loop:  
    printf("%d", i);  
    printf("\n");  
    i++;  
    if (i < 10) goto loop;  
end:
```
