

COMP1521 25T1 — MIPS Data

<https://www.cse.unsw.edu.au/~cs1521/25T1/>

The Memory Subsystem

- memory subsystem typically provides capability to load or store **bytes** (not bits)
 - 1 byte == 8 bits (on general purpose modern machines)
- each byte has unique **address**, think of:
 - memory as implementing a gigantic array of bytes
 - and the address is the array index
- typically, a small (1,2,4,8,...) group of bytes can be loaded/stored in a single operation
- general purpose computers typically have complex *cache systems* to improve memory performance
 - if we have time we'll look at cache systems a little, late in this course

Virtual Memory - Quick Summary

- we'll come back to **virtual memory** if any time left in week 10
- operating systems on general purpose computers typically provide **virtual memory**
- **virtual memory** make it look to every running program that it has entire address space
 - hugely convenient for multi-process systems
- disconnects addresses running programs (processes) use from actual RAM address.
- operating system translates (virtual) address a process uses to an physical (actual) RAM address.
- translation needs to be really fast - needs to be largely implemented in hardware (silicon)
- **virtual memory** can be several times larger than actual RAM size
- multiple processes can be in RAM, allowing fast switching
- part of processes can be load into RAM on demand.
- provides a mechanism to share memory between processes.

- most modern general purpose computers use 64-bit addresses
 - CSE servers use 64-bit addresses
- some (older) general purpose computers use 32-bit addresses
- many special purpose (embedded) CPUs use 32-bit addresses
 - but some use 64-bit addresses
 - some use 16-bit addresses
- on the MIPS32 machine implemented by `mipsy`, all addresses are 32-bit so in COMP1521 assembler we'll be using 32-bit addresses
- there are 64-bit MIPS CPUs

Accessing Memory on the MIPS

- addresses are 32 bits
- only load/store instructions access memory on the MIPS
- 1 byte (8-bit) loaded/stored with **lb/sb**
- 2 bytes (16-bit) called a **half-word**, loaded/stored with **lh/sh**
- 4 bytes (32-bits) called a **word**, loaded/stored with **lw/sw**
- memory address used for load/store instructions is sum of a specified register and a 16-bit constant (often 0) which is part of the instruction
- for **sb** & **sh** operations low (least significant) bits of source register are used.
- **lb/lh** assume byte/halfword contains a 8-bit/16-bit **signed** integer
 - high 24/16-bits of destination register set to 1 if 8-bit/16-bit integer negative
- unsigned equivalents **lbu** & **lhu** assume integer is **unsigned**
 - high 24/16-bits of destination register always set to 0
- signed and unsigned integer representations covered later in course

MIPS Load/Store Instructions

```

# simple example of load & storing a byte
# we normally use directives and labels
main:
    li $t0, 42
    li $t1, 0x10000000
    sb $t0, 0($t1)    # store 42 in byte at address 0x10000000
    lb $a0, 0($t1)    # load $a0 from same address
    li $v0, 1         # print $a0 which now contains 42
    syscall
    li $a0, '\n'     # print '\n'
    li $v0, 11
    syscall
    li $v0, 0         # return 0
    jr $ra

```

source code for load_store_no_labels

Assembler Directives

mipsy has directives to initialise memory, and to associate labels with addresses.

```

.text           # following instructions placed in text segment

.data          # following objects placed in data segment

a: .space 18    # int8_t a[18];
   .align 2     # align next object on 4-byte addr
i: .word 42     # int32_t i = 42;
v: .word 1,3,5  # int32_t v[3] = {1,3,5};
h: .half 2,4,6  # int16_t h[3] = {2,4,6};
b: .byte 7:5    # int8_t b[5] = {7,7,7,7,7};
f: .float 3.14  # float f = 3.14;
s: .asciiz "abc" # char s[4] {'a','b','c','\0'};
t: .ascii "abc" # char t[3] {'a','b','c'};

```

Code example: storing and loading a value with a label

```

# simple example of load & storing a byte
# we normally use directives and labels
# lb & sb require address in a register, but mipsy will do this for us
main:
    li $t0, 42
    sb $t0, answer    # store 42 in byte at address labelled answer
    lb $a0, answer    # load $a0 from same address
    li $v0, 1         # print $a0 which will nows contain 42
    syscall
    li $a0, '\n'     # print '\n'
    li $v0, 11
    syscall
    li $v0, 0         # return 0
    jr $ra

.data
answer:
.space 1         # set aside 1 byte and associate label answer with its address

```

```

# simple example of storing & loading a byte
main:
    li $t0, 42
    la $t1, answer
    sb $t0, 0($t1)    # store 42 in byte at address labelled answer
    lb $a0, 0($t1)    # load $a0 from same address
    li $v0, 1         # print $a0 which will now contain 42
    syscall
    li $a0, '\n'      # print '\n'
    li $v0, 11
    syscall
    li $v0, 0         # return 0
    jr $ra
    .data
answer:
    .space 1         # set aside 1 byte and associate label answer with its address

```

source code for load_stores

<https://www.cse.unsw.edu.au/~cs1521/25T1/>

COMP1521 25T1 — MIPS Data

10 / 75

Setting A Register to An Address

- Note the **la** (load address) instruction is normally used to set a register to a labelled memory address.

```
la $t8, start
```

- mipsy converts labels to addresses (numbers) before a program is run,
 - no real difference between **la** and **li** instructions
- For example, if **vec** is the label for memory address **0x10000100** then these two instructions are equivalent:

```
la $t7, vec
li $t7, 0x10000100
```

- In both cases the constant is encoded as part of the instruction(s).
- Neither **la** or **li** access memory!
They are very different to **lw** etc

<https://www.cse.unsw.edu.au/~cs1521/25T1/>

COMP1521 25T1 — MIPS Data

11 / 75

Specifying Addresses: Some mipsy short-cuts

- mipsy allows the constant which is part of load & store instructions can be omitted in the common case it is 0.

```
sb $t0, 0($t1) # store $t0 in byte at address in $t1
sb $t0, ($t1) # same
```

- For convenience, MIPSY allows addresses to be specified in a few other ways and will generate appropriate real MIPS instructions

```
sb $t0, x      # store $t0 in byte at address labelled x
sb $t1, x+15   # store $t1 15 bytes past address labelled x
sb $t2, x($t3) # store $t2 $t3 bytes past address labelled x
```

- These are effectively pseudo-instructions.
- You can use these short cuts but won't help you much
- Most assemblers have similar short cuts for convenience

<https://www.cse.unsw.edu.au/~cs1521/25T1/>

COMP1521 25T1 — MIPS Data

12 / 75

Region	Address	Notes
.text	0x00400000..	instructions only; read-only; cannot expand
.data	0x10000000..	data objects; read/write; can be expanded
.stack	..0x7ffffffe	this address and below; read/write
.ktext	0x80000000..	kernel code; read-only; only accessible in kernel mode
.kdata	0x90000000..	kernel data; only accessible in kernel mode

Data Structures and MIPS

C data structures and their MIPS representations:

- `char` ... as byte in memory, or register
- `int` ... as 4 bytes in memory, or register
- `double` ... as 8 bytes in memory, or `$f?` register
- arrays ... sequence of bytes in memory, elements accessed by index (calculated on MIPS)
- structs ... sequence of bytes in memory, accessed by fields (constant offsets on MIPS)

A `char`, `int` or `double`

- can be stored in register if local variable and no pointer to it
- otherwise stored on stack if local variable
- stored in data segment if global variable

Global Variables

Labels and *directives* used to allocate space for global variables in the `.data` segment.

```

.data
a:
    .word 16          # int a = 16;
b:
    .space 4         # int b;
c:
    .space 4         # char c[4];
d:
    .byte 1, 2, 3, 4 # char d[4] = {1, 2, 3, 4};
e:
    .byte 0:4        # char e[4] = {0, 0, 0, 0};
f:
    .asciiz "hello"  # char *f = "hello";
    .align 2
g:
    .space 4         # int g;

```

```
#include <stdio.h>
int global_counter = 0;
int main(void) {
    // Increment the global counter.
    // The following is the same as global_counter = global_counter + 1 (generally)
    global_counter++;
    printf("%d", global_counter);
    putchar('\n');
}
```

source code for global_increment.c

Incrementing a Global Variable: MIPS

```
lw $t1, global_counter
addi $t1, $t1, 1
sw $t1, global_counter # global_counter = global_counter + 1;
# Method 2: Explicitly load the address of
# global_counter into a register.
li $v0, 1 # syscall 1: print_int
la $t0, global_counter #
lw $a0, 0($t0)
syscall # printf("%d", global_counter);
li $v0, 11 # syscall 11: print_char
li $a0, '\n'
syscall # putchar('\n');
li $v0, 0
jr $ra # return 0;
.data
global_counter:
.word 0 # int global_counter = 0;
```

Computing sum of 2-d Array : C

Assume we have a 2d-array:

```
int32_t matrix[6][5];
```

We can sum its value like this in C

```

int row, col, sum = 0;
// row-by-row
for (row = 0; row < 6; row++) {
    // col-by-col within row
    for (col = 0; col < 5; row++) {
        sum += matrix[row][col];
    }
}

```

MIPS directives for an equivalent 2d-array

```

.data
matrix: .space 120 # 6 * 5 == 30 array elements each 4 bytes

```

Computing sum of 2-d Array : MIPS

COMP1521 25T1 — MIPS Data

47 / 75

Alignment

- C standard requires simple types of size N bytes to be stored only at addresses which are divisible by N
 - if `int` is 4 bytes, must be stored at address divisible by 4
 - if `double` is 8 bytes, must be stored at address divisible by 8
- compound types (arrays, structs) must be aligned so their components are aligned
- MIPS requires this alignment
- on other architectures aligned access faster

<https://www.cse.unsw.edu.au/~cs1521/25T1/>

COMP1521 25T1 — MIPS Data

48 / 75

```
char bytes[32];
int *i = (int *)&bytes[1];
// illegal store - not aligned on a 4-byte boundary
*i = 42;
printf("%d\n", *i);
```

source code for unalign.c

Example MIPS with unaligned accesses

```
.data
# data will be aligned on a 4-byte boundary
# mostlikely on at least a 128-byte boundary
# but safer to just add a .align directive
.align 2
.space 1
v1: .space 1
v2: .space 4
v3: .space 2
v4: .space 4
    .space 1
    .align 2           # ensure e is on a 4 (2**2) byte boundary
v5: .space 4
    .space 1
v6: .word 0           # word directive aligns on 4 byte boundary
```

source code for unalign.s

Example MIPS with unaligned accesses

```
li $t0, 1
sb $t0, v1           # will succeed because no alignment needed
sh $t0, v1           # will fail because v1 is not 2-byte aligned
sw $t0, v1           # will fail because v1 is not 4-byte aligned
sh $t0, v2           # will succeed because v2 is 2-byte aligned
sw $t0, v2           # will fail because v2 is not 4-byte aligned
sh $t0, v3           # will succeed because v3 is 2-byte aligned
sw $t0, v3           # will fail because v3 is not 4-byte aligned
sh $t0, v4           # will succeed because v4 is 2-byte aligned
sw $t0, v4           # will succeed because v4 is 4-byte aligned
sw $t0, v5           # will succeed because v5 is 4-byte aligned
sw $t0, v6           # will succeed because v6 is 4-byte aligned
li $v0, 0
jr $ra               # return
```

source code for unalign.s

Offset

```

struct _student {
    int    id;
    char   family[20];
    char   given[20];
    int    program;
    double wam;
};

```

Implementing Structs in MIPS

C **struct** definitions effectively define a new type.

```

// new type called "struct student"
struct student {...};

// new type called student_t
typedef struct student student_t;

```

Instances of structures can be created by allocating space:

```

                # sizeof(Student) == 56
stu1:           # student_t stu1;
                .space 56
stu2:           # student_t stu2;
                .space 56
stu:            # student_t *stu;
                .space 4

```

Implementing Structs in MIPS

Accessing structure components is by offset, not name

```

li $t0, 5012345
la $t1, stu1
sw $t0, 0($t1)      # stu1.id = 5012345;
li $t0, 3778
sw $t0, 44($t1)    # stu1.program = 3778;

la $t2, stu2       # stu = &stu2;
li $t0, 3707
sw $t0, 44($t2)    # stu->program = 3707;
li $t0, 5034567
sw $t0, 0($t2)    # stu->id = 5034567;

```

Student Details: C

```
struct details {
    uint16_t  postcode;
    uint8_t   wam;
    uint32_t  zid;
};
struct details student;
