COMP1521 26T1 — MIPS Data

https://www.cse.unsw.edu.au/~cs1521/26T1/

The Memory Subsystem

- memory subsystem typically provides capability to load or store **bytes** (not bits)
  - 1 byte == 8 bits (on general purpose modern machines)
- each byte has unique **address**, think of:
  - memory as implementing a gigantic array of bytes
  - and the address is the array index
- typically, a small (1,2,4,8,...) group of bytes can be loaded/stored in a single operation
- general purpose computers typically have complex *cache systems* to improve memory performance
  - if we have time we'll look at cache systems a little, late in this course

Virtual Memory - Quick Summary

- we'll come back to **virtual memory** if there is time in week 10
- operating systems on general purpose computers typically provide **virtual memory**
- **virtual memory** provides an abstract view of system memory; obscuring its location, size and availability
  - very convenient for multi-process systems
- decouples addresses of running programs (processes) from physical RAM address
- operating system translates (virtual) address accesses to physical RAM address
- translation needs to be really fast - typically implemented in hardware (silicon)
- **virtual memory** can be several times larger than the available RAM
- multiple processes can stay resident in RAM, allowing fast switching between processes
- part of process memory can be loaded from disk into RAM on demand
- provides a mechanism to share memory between processes

Address Size

- most modern general purpose computers use 64-bit addresses
  - CSE servers use 64-bit addresses
- some (older) general purpose computers use 32-bit addresses
- many special purpose (embedded) CPUs use 32-bit addresses
  - but some use 64-bit addresses
  - some use 16-bit addresses
- on the MIPS32 machine implemented by `mipsy`, all addresses are 32-bit
  so in COMP1521 assembler we'll be using 32-bit addresses
- there are 64-bit MIPS CPUs

Accessing Memory on the MIPS

- addresses are 32 bits
- only load/store instructions access memory on the MIPS
- 1 byte (8-bit) loaded/stored with **`lb`**/**`sb`**
- 2 bytes (16-bit) called a **half-word**, loaded/stored with **`lh`**/**`sh`**
- 4 bytes (32-bits) called a **word**, loaded/stored with **`lw`**/**`sw`**
- memory address used for load/store instructions is sum of a specified register and a 16-bit constant (often 0) which is part of the instruction
- for **`sb`** & **`sh`** operations low (least significant) bits of source register are used.
- **`lb`**/**`lh`** assume byte/halfword contains a 8-bit/16-bit **signed** integer
  - high 24/16-bits of destination register set to 1 if 8-bit/16-bit integer negative
- unsigned equivalents **`lbu`** & **`lhu`** assume integer is **unsigned**
  - high 24/16-bits of destination register always set to 0
- signed and unsigned integer representations covered later in course

MIPS Load/Store Instructions

assembly	meaning	bit pattern
lb r_t, I(r_s)	r_t = **mem**[r_s+I]	100000ssssstttttIIIIIIIIIIIIIIII
lh r_t, I(r_s)	r_t = **mem**[r_s+I] |	100001ssssstttttIIIIIIIIIIIIIIII
	mem[r_s+I+1] << 8	
lw r_t, I(r_s)	r_t = **mem**[r_s+I] |	100011ssssstttttIIIIIIIIIIIIIIII
	mem[r_s+I+1] << 8 |	
	mem[r_s+I+2] << 16 |	
	mem[r_s+I+3] << 24	
sb r_t, I(r_s)	**mem**[r_s+I] = r_t & 0xff	101000ssssstttttIIIIIIIIIIIIIIII
sh r_t, I(r_s)	**mem**[r_s+I] = r_t & 0xff	101001ssssstttttIIIIIIIIIIIIIIII
	mem[r_s+I+1] = r_t >> 8 & 0xff	
sw r_t, I(r_s)	**mem**[r_s+I] = r_t & 0xff	101011ssssstttttIIIIIIIIIIIIIIII
	mem[r_s+I+1] = r_t >> 8 & 0xff	
	mem[r_s+I+2] = r_t >> 16 & 0xff	
	mem[r_s+I+3] = r_t >> 24 & 0xff	

Code example: storing and loading a value (no labels)

```
# simple example of load & storing a byte
# we normally use directives and labels
main:
    li   $t0, 42
    li   $t1, 0x10000000
    sb   $t0, 0($t1)      # store 42 in byte at address 0x10000000
    lb   $a0, 0($t1)      # load $a0 from same address
    li   $v0, 1           # print $a0 which now contains 42
    syscall
    li   $a0, '\n'        # print '\n'
    li   $v0, 11
    syscall
    li   $v0, 0           # return 0
    jr   $ra
```

source code for load_store_no_label.s

Assembler Directives

`mipsy` has directives to initialise memory, and to associate labels with addresses.

```
    .text           # following instructions placed in text segment

    .data           # following objects placed in data segment

a:  .space 18       # int8_t a[18];
    .align 2        # align next object on 4-byte addr
i:  .word 42        # int32_t i = 42;
v:  .word 1,3,5     # int32_t v[3] = {1,3,5};
h:  .half 2,4,6     # int16_t h[3] = {2,4,6};
b:  .byte 7:5       # int8_t b[5] = {7,7,7,7,7};
f:  .float 3.14     # float f = 3.14;
s:  .asciiz "abc"   # char s[4] {'a','b','c','\0'};
t:  .ascii "abc"    # char t[3] {'a','b','c'};
```

Code example: storing and loading a value with a label

```
# simple example of load & storing a byte
# we normally use directives and labels
# lb & sb require address in a register, but mipsy will do this for us
main:
    li   $t0, 42
    sb   $t0, answer      # store 42 in byte at address labelled answer
    lb   $a0, answer      # load $a0 from same address
    li   $v0, 1           # print $a0 which will nows contain 42
    syscall
    li   $a0, '\n'        # print '\n'
    li   $v0, 11
    syscall
    li   $v0, 0           #  return 0
    jr   $ra
.data
answer:
    .space 1              # set aside 1 byte and associate label answer with its
```

Code example: storing and loading a value with address in register

```
# simple example of storing & loading a byte
main:
    li   $t0, 42
    la   $t1, answer
    sb   $t0, 0($t1)      # store 42 in byte at address labelled answer
    lb   $a0, 0($t1)      # load $a0 from same address
    li   $v0, 1           # print $a0 which will nows contain 42
    syscall
    li   $a0, '\n'        # print '\n'
    li   $v0, 11
    syscall
    li   $v0, 0           # return 0
    jr   $ra
    .data
answer:
    .space 1              # set aside 1 byte and associate label answer with its ad
```

source code for load_store.s

Setting A Register to An Address

- Note the **la** (load address) instruction is normally used to set a register to a labelled memory address.

```
    la $t8, start
```

- mipsy converts labels to addresses (numbers) before a program is run,
  - no real difference between **la** and **li** instructions
- For example, if **vec** is the label for memory address **0x10000100** then these two instructions are equivalent:

```
    la  $t7, vec
    li  $t7, 0x10000100
```

- In both cases the constant is encoded as part of the instruction(s).
- Neither **la** or **li** access memory!
  They are *very* different to **lw** etc

Specifying Addresses: Some `mipsy` short-cuts

- `mipsy` allows the constant which is part of load & store instructions can be omitted in the common case it is 0.

```
sb $t0, 0($t1) # store $t0 in byte at address in $t1
sb $t0, ($t1)  # same
```

- For convenience, MIPSY allows addresses to be specified in a few other ways and will generate appropriate real MIPS instructions

```
sb $t0, x      # store $t0 in byte at address labelled x
sb $t1, x+15   # store $t1 15 bytes past address labelled x
sb $t2, x($t3) # store $t2 $t3 bytes past address labelled x
```

- These are effectively pseudo-instructions.
- You can use these short cuts but won't help you much
- Most assemblers have similar short cuts for convenience

MIPSY Memory Layout

Region	Address	Notes
`.text`	**`0x00400000`**..	instructions only; read-only; cannot expand
`.data`	**`0x10000000`**..	data objects; read/write; can be expanded
`.stack`	..**`0x7fffffef`**	this address and below; read/write
`.ktext`	**`0x80000000`**..	kernel code; read-only; only accessible in kernel mode
`.kdata`	**`0x90000000`**..	kernel data; only accessible in kernel mode

Data Structures and MIPS

C data structures and their MIPS representations:

- `char` ... as byte in memory, or register
- `int` ... as 4 bytes in memory, or register
- `double` ... as 8 bytes in memory, or `$f?` register
- arrays ... sequence of bytes in memory, elements accessed by index (calculated on MIPS)
- structs ... sequence of bytes in memory, accessed by fields (constant offsets on MIPS)

A `char`, `int` or `double`

- can be stored in register if local variable and no pointer to it
- otherwise stored on stack if local variable
- stored in data segment if global variable

Global Variables

Labels and ***directives*** used to allocate space for global variables in the `.data` segment.

```
    .data
a:
    .word   16          # int a = 16;
b:
    .space  4           # int b;
c:
    .space  4           # char c[4];
d:
    .byte   1, 2, 3, 4      # char d[4] = {1, 2, 3, 4};
e:
    .byte   0:4         # char e[4] = {0, 0, 0, 0};
f:
    .asciiz "hello"         # char *f = "hello";
    .align  2
g:
    .space  4           # int g;
```

source code for sample_data.s

Incrementing a Global Variable: C

```c
#include <stdio.h>
int global_counter = 0;
int main(void) {
    // Increment the global counter.
    // The following is the same as global_counter = global_counter + 1 (generall
    global_counter++;
    printf("%d", global_counter);
    putchar('\n');
}
```

source code for global_increment.c

Incrementing a Global Variable: MIPS

```
    lw  $t1, global_counter
    addi    $t1, $t1, 1
    sw  $t1, global_counter # global_counter = global_counter + 1;
    # Method 2: Explicitly load the address of
    # global_counter into a register.
    li  $v0, 1          # syscall 1: print_int
    la  $t0, global_counter #
    lw  $a0, 0($t0)
    syscall             # printf("%d", global_counter);
    li  $v0, 11         # syscall 11: print_char
    li  $a0, '\n'
    syscall             # putchar('\n');
    li  $v0, 0
    jr  $ra         # return 0;
    .data
global_counter:
    .word   0               # int global_counter = 0;
```

source code for global_increment.s

add: local variables in registers

C

```c
int main(void) {
    int x, y, z;
    x = 17;
    y = 25;
    z = x + y;
    // ...
```

MIPS

```
main:
    # x in $t0
    # y in $t1
    # z in $t2

```

store value in array element — example 1

C

```c
int x[10];

int main(void) {
    // sizeof x[0] == 4
    x[3] = 17;
}
```

MIPS

```
main:
    li   $t0, 3

    # each array element is 4 bytes
    mul  $t0, $t0, 4
    la   $t1, x
    add  $t2, $t1, $t0
    li   $t3, 17
    sw   $t3, 0($t2)
.data
x:  .space 40
```

store value in array element - example 2

C

```c
#include <stdint.h>

int16_t x[30];

int main(void) {
    // sizeof x[0] == 2
    x[13] = 23;
}
```

MIPS

```
main:
    li   $t0, 13

    # each array element is 2 bytes
    mul  $t0, $t0, 2
    la   $t1, x
    add  $t2, $t1, $t0
    li   $t3, 23
    sh   $t3, 0($t2)
.data
x:  .space 60
```

Printing Array: C to simplified C

C

```c
int main(void) {
    int i = 0;
    while (i < 5) {
        printf("%d\n", numbers[i]);
        i++;
    }
    return 0;
}
```

source code for print5.c

Simplified C

```c
int main(void) {
    int i = 0;
loop:
    if (i >= 5) goto end;
        int n = numbers[i];
        printf("%d", n);
        printf("%c", '\n');
        i++;
    goto loop;
end:
    return 0;
}
```

source code for print5.simple.c

Printing Array: MIPS

```
# print array of ints
# register use
# - $t0: int i
# - $t1: int n
# - $t5..$t7: temporary results
main:
    li  $t0, 0          # int i = 0;
loop_1:
    bge $t0, 5, end_1       # if (i >= 5) goto end_1;
    la  $t5, numbers        #    int n = numbers[i];
    mul $t6, $t0, 4
    add $t7, $t5, $t6
    lw  $t1, 0($t7)
    move    $a0, $t1        #    printf("%d", n);
    li  $v0, 1
    syscall
    li  $a0, '\n'       #    printf("%c", '\n');
```

Printing Array: MIPS (continued)

```
end_1:
    li   $v0, 0           # return 0
    jr   $ra
    .data
numbers:                  # int numbers[10] = { 3, 9, 27, 81, 243};
    .word 3, 9, 27, 81, 243
```

source code for print5.s

Changing an Array: C

```c
int i;
i = 0;
while (i < 5) {
    numbers[i] *= 42;
    i++;
}
```

source code for change_array.c

Changing an Array MIPS

```
# i in register $t0
# registers $t1..$t3 used to hold calculations
main:
    li   $t0, 0           # i = 0
loop1:
    bge  $t0, 5, end1  # while (i < 5) {
    mul  $t1, $t0, 4     #
    la   $t2, numbers    # calculate &numbers[i]
    add  $t1, $t1, $t2   #
    lw   $t3, ($t1)      # load numbers[i] into $t3

```

Computing sum of 2-d Array : C

Assume we have a 2d-array:

```
int32_t matrix[6][5];
```

We can sum its value like this in C

```
int row, col, sum = 0;
// row-by-row
for (row = 0; row < 6; row++) {
   // col-by-col within row
   for (col = 0; col < 5; row++) {
      sum += matrix[row][col];
   }
}
```

MIPS directives for an equivalent 2d-array

```
    .data
matrix: .space 120 # 6 * 5 == 30 array elements each 4 bytes
```

Computing sum of 2-d Array : MIPS

```
        li   $t0, 0             # sum = 0
        li   $t1, 0             # row = 0
loop1:  bge  $t1, 6, end1       # if (row >= 6) break
        li   $t2, 0             # col = 0
loop2:  bge  $t2, 5, end2       # if (col >= 5) break
        la   $t3, matrix
        mul  $t4, $t1, 20       # t1 = row*rowsize
        mul  $t5, $t2, 4        # t2 = col*intsize
        add  $t6, $t3, $t4      # offset = t0+t1
        add  $t7, $t6, $t5      # offset = t0+t1
        lw   $t5, 0($t7)        # t0 = *(matrix+offset)
        add  $t0, $t0, $t5      # sum += t0
        addi $t2, $t2, 1        # col++
        j    loop2
end2:   addi $t1, $t1, 1        # row++
        j    loop1
end1:
```

Printing 2-d Array: C to simplified C

C

```c
int main(void) {
    int i = 0;
    while (i < 3) {
        int j = 0;
        while (j < 5) {
            printf("%d", numbers[i][j]);
            printf("%c", ' ');
            j++;
        }
        printf("%c", '\n');
        i++;
    }
    return 0;
}
```

Alignment

- C standard requires simple types of size N bytes to be stored only at addresses which are divisible by N
  - if `int` is 4 bytes, must be stored at address divisible by 4
  - if ‘double is 8 bytes, must be stored at address divisible by 8
- compound types (arrays, structs) must be aligned so their components are aligned
- MIPS requires this alignment
- on other architectures aligned access faster

Example C with unaligned accesses

```c
char bytes[32];
int *i = (int *)&bytes[1];
// illegal store - not aligned on a 4-byte boundary
*i = 42;
printf("%d\n", *i);
```

source code for unalign.c

Example MIPS with unaligned accesses

```
    .data
    # data will be aligned on a 4-byte boundary
    # most likely on at least a 128-byte boundary
    # but safer to just add a .align directive
    .align 2
    .space 1
v1: .space 1
v2: .space 4
v3: .space 2
v4: .space 4
    .space 1
    .align 2            # ensure e is on a 4 (2**2) byte boundary
v5: .space 4
    .space 1
v6: .word 0             # word directive aligns on 4 byte boundary
```

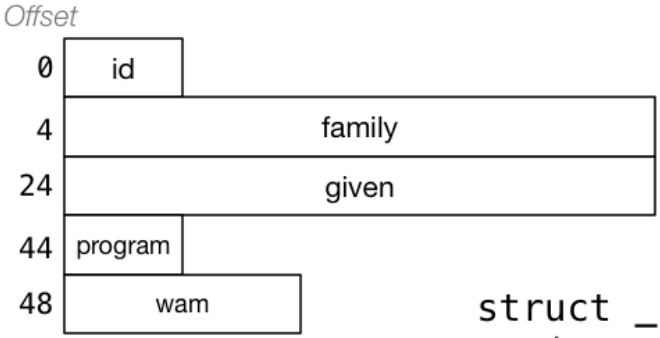
source code for unalign.s

Example MIPS with unaligned accesses

```
li   $t0, 1
sb   $t0, v1          # will succeed because no alignment needed
sh   $t0, v1          # will fail because v1 is not 2-byte aligned
sw   $t0, v1          # will fail because v1 is not 4-byte aligned
sh   $t0, v2          # will succeeed because v2 is 2-byte aligned
sw   $t0, v2          # will fail because v2 is not 4-byte aligned
sh   $t0, v3          # will succeeed because v3 is 2-byte aligned
sw   $t0, v3          # will fail because v3 is not 4-byte aligned
sh   $t0, v4          # will succeeed because v4 is 2-byte aligned
sw   $t0, v4          # will succeeed because v4 is 4-byte aligned
sw   $t0, v5          # will succeeed because v5 is 4-byte aligned
sw   $t0, v6          # will succeeed because v6 is 4-byte aligned
li   $v0, 0
jr   $ra          # return
```

source code for unalign.s

Structs in MIPS



```
struct _student {
    int    id;
    char   family[20];
    char   given[20];
    int    program;
    double wam;
};
```

Implementing Structs in MIPS

C **struct** definitions effectively define a new type.

```
// new type called "struct student"
struct student {...};

// new type called student_t
typedef struct student student_t;
```

Instances of structures can be created by allocating space:

```
                # sizeof(Student) == 56
stu1:           # student_t stu1;
    .space 56
stu2:           # student_t stu2;
    .space 56
stu:
    .space 4    # student_t *stu;
```

Implementing Structs in MIPS

Accessing structure components is by offset, not name

```
li   $t0  5012345
la   $t1, stu1
sw   $t0, 0($t1)        # stu1.id = 5012345;
li   $t0, 3778
sw   $t0, 44($t1)       # stu1.program = 3778;

la   $t2, stu2          # stu = &stu2;
li   $t0, 3707
sw   $t0, 44($t2)       # stu->program = 3707;
li   $t0, 5034567
sw   $t0, 0($t2)        # stu->id = 5034567;
```

Student Details: C

```c

Printing Array with Pointers: C to simplified C

C

```c
int main(void) {
    int *p = &numbers[0];
    int *q = &numbers[4];
    while (p <= q) {
        printf("%d\n", *p);
        p++;
    }
    return 0;
}
```

source code for pointer5.c

Simplified C

```c
int main(void) {
    int *p = &numbers[0];
    int *q = &numbers[4];
loop:
    if (p > q) goto end;
        int j = *p;
        printf("%d", j);
        printf("%c", '\n');
        p++;
    goto loop;
end:
    return 0;
}
```

source code for pointer5.simple.c

Printing Array with Pointers: MIPS

```
# register use
# - $t0: int *p
# - $t1: int *q
main:
    la   $t0, numbers         # int *p = &numbers[0];
    la   $t0, numbers         # int *q = &numbers[4];
    addi    $t1, $t0, 16        #
loop:
    bgt $t0, $t1, end         # if (p > q) goto end;
    lw   $a0, 0($t0)      # int j = *p;
    li   $v0, 1
    syscall
    li   $a0, '\n'        #   printf("%c", '\n');
    li   $v0, 11
    syscall
    addi    $t0, $t0, 4       #   p++
```

Printing Array with Pointers: MIPS - faster

```
# p in $t0
# q in $t1
main:
    la  $t0, numbers        # int *p = &numbers[0];
    addi    $t1, $t0, 16        # int *q = &numbers[4];
loop:
    lw  $a0, 0($t0)     # printf("%d", *p);
    li  $v0, 1
    syscall
    li  $a0, '\n'       #   printf("%c", '\n');
    li  $v0, 11
    syscall
    addi    $t0, $t0, 4     #   p++
    ble $t0, $t1, loop      # if (p <= q) goto loop;
```
