Shells

- Shells are command interpreters
  - they allow interactive users to execute the commands.
  - typically a command causes another program to be run
- shells may have a graphical (point-and-click) interface
  - e.g. Windows or Mac desktop
  - much easier for naive users
  - much less powerful & not covered in this course
- command-line shells are programmable, powerful tools for expert users
- **bash** is the most popular used shell for unix-like systems
- other significant unix-like shells include: **dash, zsh, fish, busybox**
- we will cover the core features provided by all shells
  - essentially the POSIX standard shell features

What Shells Do

- Unix shells have the same basic mode of operation:

  ```
  loop
  if (interactive) print a prompt
  read a line of user input
  apply transformations to line
  split line into words using whitespace
  use first word in line as command name
  execute command, passing other words as arguments
  end loop
  ```

- shells can also be run with commands in a file
- shells are programming languages
- shells have design decisions to suit interactive use
  - e.g. variables don't have to be initialized or declared
  - these decisions not ideal for programming in Shell
  - in other words there have to be design compromises
Processing a Shell Input Line

- a series of **transformations** are applied to Shell input lines
  - tilde expansion, e.g. `~z1234567` → `/home/z1234567`
  - parameter and variable expansion, e.g. `$HOME` → `/home/z1234567`
  - arithmetic expansion, e.g. `$((6 * 7))` → 42
  - command substitution, e.g. `$WHOAMI` → `z1234567`
  - word splitting - line is broken up on white-space
  - filename expansion (globbing), e.g. `*.c` → `main.c i.c`
  - I/O redirection e.g. `<i.txt` → stdin replaced with stream from `i.txt`
  - first word used as program name, other words passed as arguments

- order of these transformations is important!
- not understanding order is a common source of bugs & security holes
  - directories in **PATH** searched for program name

---

echo: print arguments to stdout

- **echo** prints its arguments to stdout
- mainly used in scripts, but also useful when exploring shell behaviour
- **echo** is often built in to shells for efficiency, but also provided by `/bin/echo`
- see also `/usr/bin/printf`
- Two useful **echo** options:
  - `-n` do not output a trailing newline
  - `-e` enable interpretation of backslash escapes (on by default in dash)

```bash
$ echo Hello Andrew
Hello Andrew
$ echo '

'
$ echo -e '

'

$ echo -n Hello Andrew
Hello Andrew$
```

---

echo: implemented in Python

```python
import sys
def main():
    ""
    print arguments to stdout
    ""
    print(' '.join(sys.argv[1:]))
```

source code for echo.py
```c
// print arguments to stdout
int main(int argc, char *argv[]) {
    for (int i = 1; i < argc; i++) {
        if (i > 1) {
            fputc(' ', stdout);
        }
        fputs(argv[i], stdout);
    }
    fputc('
', stdout);
    return 0;
}
```

**Shell Variables**

- Shell variables are untyped - consider them as strings
  - Note that 1 is equivalent to "1"
- Shell variables are not declared
- Shell variables do not need initialization
  - Initial value is the empty string
- One scope - no local variables
  - Except sub-shells & functions (sort-of)
  - Changes to variables in sub-shells have no effect outside sub-shell
  - Components of pipeline executed in sub-shell
- `$name` replaced with value of variable `name`
- `name=value` assigns `value` to variable `name`
  - Note: no spaces around `=`

**$(command)** - command expansion:

- `$(command)` is evaluated by running `command`
- Stdout is captured from `command`
- `$(command)` is replaced with the entire captured stdout
- `'(command)'` (backticks) is equivalent to `$(command)`
  - Backticks is original syntax, so widely used
  - Nesting of backticks is problematic

For example:

```
$ now=$(date)
$ echo $now
Sun 23 Jun 1912 02:31:00 GMT
$```
'' - Single Quotes

- single quotes '' group the characters within into a single word
- no characters interpreted specially inside single quotes
- variables, commands and arithmetic are not expanded inside single quotes
- globbing and word-splitting does not occur inside double quotes
- a single quote can not occur within single quotes
- you can put a double quote between single-quotes

For example:

$ echo '*** !@#$%^&*(){}[]:"<>?,./` ***'
*** !@#$%^&*(){}[]:"<>?,./`
$ echo 'this is "normal"'
this is "normal"

"" - Double Quotes

- double quotes "" group the characters within into a single word
- variables, commands and arithmetic are expanded inside double quotes
- backslash can be used to escape $" "
- other characters not interpreted specially inside double quotes
- globbing and word-splitting does not occur inside double quotes
- you can put a single quote between double-quotes

For example:

$ answer=42
$ echo "The answer is $answer." 
The answer is 42.
$ echo 'The answer is $answer.'
The answer is $answer.
$ echo "time's up"
time's up
$ echo "* *
* *"

<< - here documents

- <<word called a here document
- following lines until word specify multi-line string as command input
- variables and commands expanded - same as double quotes
- <<word variables and commands not expanded - same as single quotes
- <<word removes leading tabs from each line, allowing indentation within scripts

$ name=Andrew
$ tr a-z A-Z <<END-MARKER
Hello $name
How are you
Good bye
END-MARKER
HELLO ANDREW
HOW ARE YOU
GOOD BYE
Arithmetic

- `$((expression))` is evaluated as an arithmetic expression
  - `expression` is evaluated as C-like integer arithmetic
  - and is replaced with the result
  - the `$` on variables can be omitted in expressions
- shell arithmetic implementation slow compared to e.g. C
  - significant overhead converting to/from strings
- older scripts may use the separate program `expr` for arithmetic

For example:

```bash
$ x=8
$ answer=$((x*x - 3*x + 2))
$ echo $answer
42
```

- Note that variables in arithmetic expressions are recursively evaluated

word splitting

- coders not understanding how shells split words is a frequent source of bugs

```bash
# inspect how shell splits lines into program arguments (argv)
import sys
print(f'sys.argv = {sys.argv}')
```

```bash
$ v=''
$ ./print_argv.py $v
sys.argv = ['./print_argv.py']
$ ./print_argv.py "$v"
sys.argv = ['./print_argv.py', '']
$ w=' xx yyy zzzz '
$ ./print_argv.py $w
sys.argv = ['./print_argv.py', 'xx', 'yyy', 'zzzz']
$ ./print_argv.py "$w"
sys.argv = ['./print_argv.py', ' xx yyy zzzz ']
```

*?[]! - pathname globbing

- *?[]! characters cause a word to be matched against pathnames
  - confusingly similar to regexes - but much less powerful
- * matches 0 or more of any character - equivalent to regex .*
- ? matches any one character - equivalent to regex .
- `[characters]` matches 1 of characters - same as regex []
- `[!characters]` matches 1 character not in characters - same as regex [^]
- if no pathname matches the word is unchanged
- aside: globbing also available in Python, Perl, C & other languages

```bash
$ echo *.ch
functions.c functions.h i.h main.c
$ ./print_argv.py *.ch
['./print_argv.py', 'functions.c', 'functions.h', 'i.h', 'main.c']
$ ./print_argv.py '*.[ch]
['./print_argv.py', '*.[ch]']
```

```bash
$ echo *.zzzzz
['./print_argv.py', '*.zzzzz']
```
I/O Redirection

- stdin, stdout & stderr for a command can be directed to/from files

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt; infile</code></td>
<td>connect stdin to the file <code>infile</code></td>
</tr>
<tr>
<td><code>&gt; outfile</code></td>
<td>send stdout to the file <code>outfile</code></td>
</tr>
<tr>
<td><code>&gt;&gt; outfile</code></td>
<td>append stdout to the file <code>outfile</code></td>
</tr>
<tr>
<td><code>2&gt; outfile</code></td>
<td>send stderr to the file <code>outfile</code></td>
</tr>
<tr>
<td><code>2&gt;&gt; outfile</code></td>
<td>append stderr to the file <code>outfile</code></td>
</tr>
<tr>
<td><code>&gt; outfile 2&gt;&amp;1</code></td>
<td>send stderr+stdout to file <code>outfile</code></td>
</tr>
<tr>
<td><code>&lt;&amp;2</code></td>
<td>send stderr to stdin (handy for error messages)</td>
</tr>
<tr>
<td><code>&lt;&lt; string</code></td>
<td>(in bash) here-string - a single line here-document</td>
</tr>
<tr>
<td><code>&amp;&gt; outfile</code></td>
<td>(in bash) send stdout+stderr to file <code>outfile</code></td>
</tr>
</tbody>
</table>

- beware: `>` truncates file before executing command.
- always have backups!

Pipelines

- `command | command_2 | command_3 | ...`
- stdout of `command_{n-1}` connected to stdin of `command_n`
- beware changes to variables in pipeline are lost
- some non-filter style Unix programs given a filename - read from stdin
  - allows them to be used in a pipeline

searching PATH for the program

- first word on line specifies command to be run
- if first word is not the full (absolute) pathname of a file the colon-separated list of directory specified by the variable PATH is searched
- for example if `PATH=/bin:/usr/bin:/home/z1234567/bin` and the command is `kitten` the shell will check (stat) these files in order:
  - `/bin/kitten`, `/usr/bin/kitten`, `/home/z1234567/bin`
  - the first that exists and is executable will be run
  - if none exist the shell will print an error message
- or `.` in PATH causes the current directory to be checked
  - this can be convenient - but make it last not first, e.g.:
  - `PATH=/bin:/usr/bin:/home/z1234567/bin:`
  - definitely do not include the current directory in PATH if you are root
  - an empty entry in PATH is equivalent to `.`
danger of having . in your PATH

- if . is not last in PATH then programs in the current directory may be unexpectedly run
- this can also happen inside run shell scripts or other programs you run
- robust shell scripts often set PATH to ensure this doesn't happen, e.g.: PATH=/bin:/usr/bin:$PATH

```bash
# equivalent to PATH=.:/bin:/usr/bin:/home/z1234567/bin
$ PATH=.:/bin:/usr/bin:/home/z1234567/bin
$ cat >cat <<eof
/bin/dash
echo miaou
eof
$ chmod 755 cat
cat /home/cs2041/public_html/index.html
miaou
$ 
```

Problem: ./cat is being run rather /bin/cat

Shell Scripts

We can execute shell commands in a file:

```bash
$ cat hello
echo Hello, John Connor - the time is $(date)
$ dash hello
Hello, John Connor - the time is Fri 29 Aug 1997 02:14:00 EST
```

- Unix-like systems allow an interpreter to be specified in a #! line
- allows program to be executed directly without knowing it is shell

```bash
$ cat hello
#!/usr/bin/env dash
echo Hello, John Connor - the time is $(date)
$ chmod 755 hello
$ ./hello
Hello, John Connor - the time is Fri 29 Aug 1997 02:14:00 EST
```

- use #!/bin/bash if you want bash

Shell Built-in Variables

Some shell built-in variables with pre-assigned values:

- `$0` the name of the command
- `$1` the first command-line argument
- `$2` the second command-line argument
- ... the ... command-line arguments
- `#$` count of command-line arguments
- `"$@"` command-line arguments separately (normally what you want)
- `"$*"` command-line arguments as one strings
- `$?` exit status of the most recent command
- `$$` process ID of this shell

- `$$` is useful for generating (somewhat) unique names in scripts.
- see also the shift command
Example - Shell Script using Built-in Variables

```bash
#!/bin/dash
# A simple shell script demonstrating access to arguments.
# written by andrewt@unsw.edu.au as a COMP(2041|9044) example

echo My name is "$0"
echo My process number is $$
echo I have $# arguments
# you're not going to see any difference unless you use these in a loop
echo My arguments together are "$*"
echo My arguments as quoted are "$@
echo My 5th argument is "'$5'"
echo My 10th argument is "'{10}'"
echo My 255th argument is "'{255}'"
```

source code for args.sh

https://www.cse.unsw.edu.au/~cs2041/23T2/ COMP(2041|9044) 22 / 79

Example - Simple Shell Script

```bash
#!/bin/sh
# l [file|directories...] - list files
#
# written by andrewt@unsw.edu.au as a COMP(2041|9044) example
#
# Short shell scripts can be used for convenience.
#
# It is common to put these scripts in a directory
# such as /home/z1234567/scripts
# then add this directory to PATH e.g in .bash_login
# PATH=$PATH:/home/z1234567/scripts
#
# Note: "$@" expands to the arguments to the script,
# but preserves whitespace in arguments.
ls -las "$@"
```

source code for l

https://www.cse.unsw.edu.au/~cs2041/23T2/ COMP(2041|9044) 23 / 79

Example - Putting a Pipeline in a Shell Script

```bash
#!/bin/dash
# Count the number of times each different word occurs
# in the files given as arguments, or stdin if no arguments,
# e.g. word_frequency.sh dracula.txt
# written by andrewt@unsw.edu.au as a COMP(2041|9044) example

cat "$@" | # tr doesn't take filenames as arguments
tr '[:upper:]' '[:lower:]' | # map uppercase to lower case
tr '' '\n' | # convert to one word per line
tr -cd "a-z" | # remove all characters except a-z and '
grep -E -v '^$' | # remove empty lines
sort | # place words in alphabetical order
uniq -c | # count how many times each word occurs
sort -rn # order in reverse frequency of occurrence

# notes:
# first 2 tr commands could be combined
# sed 's/ \n/g' could be used instead of tr '' '
'
# sed "s/[a-z]/g" could be used instead of tr -cd "a-z"
```

source code for word_frequency.sh

https://www.cse.unsw.edu.au/~cs2041/23T2/ COMP(2041|9044) 24 / 79
Debugging Shell Scripts

Tip: debugging for shell scripts

- test parts of shell script from command line
- use `echo` to print the value of variables
- add `set -x` to see commands being executed
  - or equivalently run `/bin/dash -x script.sh`
  - shell transforms commands
  - useful to see exactly what is being executed

Exit Status and Control

- when Unix-like programs finish they give the operating system an **exit status**
  - the return value of `main` becomes the exit status of a C program
  - `exit` is called, its argument is the exit status
  - in Python exit status is supplied as an argument to `sys.exit`
- an **exit status** is a (usually small) integer
  - by convention a zero exit status indicated normal/successful execution
  - a non-zero exit status indicates an error occurred
  - which non-zero integer might indicate the nature of the problem
- program exit status is often ignored
  - not important writing single programs (COMP1511/COMP9021)
  - very important when combining multiple programs COMP(2041|9044)
- flow of execution in Shell scripts based on exit status
  - `if/while` statement conditions use exit status
- two weird utilities
  - `/bin/true` does nothing and always exits with status 0
  - `/bin/false` does nothing and always exits with status 1

The `test` command

- The **test** command performs a test or combination of tests and:
  - does/prints nothing
  - returns a zero exit status if the test succeeds
  - returns a non-zero exit status if the test fails
- Provides a variety of useful operators:
  - string comparison: `= !=`
  - numeric comparison: `-eq -ne -lt`
  - test if file exists/is executable/is readable: `-f -x -r`
  - boolean operators (and/or/not): `-a -o !`
- also available as `[` instead of `test` - which many programmers prefer
- builtin to some shell (e.g. bash) but available as `/bin/test` or `/bin/[`
The test command examples

# does the variable msg have the value "Hello"
```
$test "msg" = "Hello"
```

# does x contain a numeric value larger than y?
```
test "$x" -gt "$y"
```

# Error: expands to "test hello there = Hello"
```
msg="hello there"
test $msg = Hello
```

# is the value of x in range 10..20?
```
test "$x" -ge 10 -a "$x" -le 20
```

# is the file xyz a readable directory?
```
test -r xyz -a -d xyz
```

# alternative syntax; requires closing ]
```
[ -r xyz -a -d xyz ]
```

If Statements - syntax

```
if command1
then
  then-commands
elif command2
then
  elif-commands
else
  else-commands
fi
```

- The execution path depends on the exit status of `command1`, and `command2`
- If `command1` is executed and its exit status is 0,
  - the `then-commands` are executed
- If otherwise `command2` is executed and its exit status is 0,
  - the `elif-commands` are executed
- Otherwise the `else-commands` are executed

If Statements - Example

```
if gcc main.c; then
  echo your C compiles
elif python3 main; then
  echo you have written Python not C
else
  echo program broken - send help
fi
```

```
if gcc a.c
then
  # you can not have an empty body
  # use a : statement which does nothing
  :
else
  rm a.c
fi
```
shell **while** statements have this form:

```
while command
do
  body-commands
done
```

- the execution path depends on the exit status of *command*
- *command* is executed and if its exit status is 0, the *body-commands* are executed and then *command* is executed and if its exit status is 0 the *body-commands* are executed and...
- if the exit status of *command* is not 0, execution of the loop stops

### example - seq - simple version

```bash
#!/bin/dash
# simple emulation of /usr/bin/seq for a COMP(2041|9044) example
# andrewt@unsw.edu.au
# Print the integers 1..n with no argument checking
last=$1
number=1
while test $number -le "$last"
do
  echo $number
  number=$((number + 1))
done
```

```
$ ./seq.v0.sh 3
1
2
3
```

### example - seq - argument handling added

```bash
#!/bin/dash
# Print the integers 1..n or n..m
if test $# = 1
then
  first=1
  last=$1
elif test $# = 2
then
  first=$1
  last=$2
else
  echo "Usage: $0 <last> or $0 <first> <last>" 1>&2
  exit 1
fi
number=$first
while test $number -le "$last"
do
  echo $number
  number=$((number + 1))
done
```

source code for seq.v1.sh
example - seq - using [] instead of test

```bash
if [ $# = 1 ]
then
    first=1
    last=$1
elif [ $# = 1 ]
then
    first=$1
    last=$2
else
    echo "Usage: $0 <last> or $0 <first> <last>" 1>&2
    exit 1
fi

number=$first
while [ $number -le $last ]
do
    echo $number
    number=$((number + 1))
done
```

source code for seq.v2.sh

example - watching a website - argument checking

```bash
# Repeatedly download a specified web page
# until a specified regexp matches its source
# then notify the specified email address.
#
# For example:
# watch_website.sh http://ticketek.com.au/ 'Ke[sS$]+ha' andrewt@unsw.edu.au
# repeat_seconds=300  #check every 5 minutes
# if test $# = 3
# then
#    url=$1
#    regexp=$2
#    email_address=$3
# else
#    echo "Usage: $0 <url> <regex> <email-address>" 1>&2
#    exit 1
#fi
```

source code for watch_website.sh

example - watching a website - main loop

```bash
while true
 do
    if curl --silent "$url" | grep -E ""$regexp" >/dev/null
    then
        # the 2nd echo is for testing, remove to really send email
        echo "Generated by $0" |
        echo mail -s "website '$url' now matches regex '$regexp'" "$email_address"
    fi
    sleep $repeat_seconds
 done
```

source code for watch_website.sh
shell for statements have this form:

```bash
for var in word1 word2 word3
do
    body-commands
...
done
```

- the loop executes once for each word with var set to the word
- break & continue statements can be used inside for & while loops with the same effect as C/Python
- keywords such for, if, while, ... are only recognised at the start of a command, e.g.:

```bash
$ echo when if else for
when if else for
```

### Example - Shell Script accessing Command-line Arguments

```bash
# Example - Shell Script accessing Command-line Arguments

echo 'Using $*:
for a in $*
do
    echo "$a"
done
echo 'Using "$*":
for a in "$*"
do
    echo "$a"
done
# This is the way to loop over command-line arguments
echo 'Using "$@":
for a in "$@
```

do
    echo "$a"
done
```

### Example - Shell Script accessing Command-line Arguments

```bash
$ ./accessing_args.sh one two "three four"
Using "$@":
Using $*:
one
two
three four
Using "$*":
one two three four
Using "$@":
one
two
three four
```

### Using Exit Status for Conditional Execution

- all commands are executed if separated by ; or newline, e.g:
  ```bash
  cmd1 ; cmd2 ; ... ; cmd_n
  ```
  - when commands are separated by &&
    ```bash
    cmd1 && cmd2 && ... && cmd_n
    ```
    execution stops if a command has non-zero exit status
    - cmd_n+1 is executed only if cmd_n has zero exit status
- when commands are separated by ||
  ```bash
  cmd1 || cmd2 || ... || cmd_n
  ```
  execution stops if a command has non-zero exit status
  - cmd_n+1 is executed only if cmd_n has non-zero exit status
- {} can be used to group commands
- () also can be used to group commands - but executes them in a subshell
  ```bash
  changes to variables and current working directory have no effect outside the subshell
  ```
- exit status of group or pipeline of commands is exit status of last command
Conditional Execution Examples

```bash
# run a.out if it exists and is executable
test -x a.out && ./a.out

# if directory tmp doesn't exist create it
(test -d tmp) || mkdir tmp

# if directory tmp doesn't exist create it
(test -d tmp) ||
  mkdir tmp
{
  chmod 755 tmp
}

# but simpler is
mkdir -p tmp && chmod 755 tmp
```

{} versus () - example

```bash
$ cd /usr/share
$ x=123
$ ( cd /tmp; x=abc; )
$ echo $x
123
$ pwd
/usr/share
$ { cd /tmp; ...
$ echo $x
abd
$ pwd
/tmp
```

- changes to variables and current working directory have no effect outside a subshell
- pipelines also executed in subshell, but variables and directory not usually changed in a pipeline

shellcheck - shell static analysis tool

- shellcheck https://www.shellcheck.net/ statically analyzes shell scripts
  - finds possible bugs without running script
  - highly-recommended because it picks up many common shell coding mistakes
- static analysis tools highly valuable because they give another way of checking for errors
  - faster/easier than testing
  - may find errors testing will miss
- static analysis tools available for many languages
  - e.g. pyflakes, pylint, prospector for Python
  - compilers (e.g. gcc/clang) use static analysis to produce faster/smaller code and report possible bugs
# Change the names of the specified files to lower case.
# (simple version of the perl utility rename)
#
# Note use of test to check if the new filename is unchanged.
#
# Note the double quotes around $filename so filenames containing spaces are not broken into multiple words
# Note the use of mv -- to stop mv interpreting a filename beginning with - as an option
# Note files named -n or -e still break the script because echo will treat them as an option,

if test $# = 0
then
    echo "Usage $0: <files>" 1>&2
    exit 1
fi

for filename in "$@"
do
    new_filename=$(echo "$filename" | tr '[:upper:]' '[:lower:]')
    test "$filename" = "$new_filename" && continue
    if test -r "$new_filename"
    then
        echo "$0: $new_filename exists" 1>&2
        elif test -e "$filename"
    then
        mv -- "$filename" "$new_filename"
    else
        echo "$0: $filename not found" 1>&2
    fi

done

$ read v
hello world
$ echo "$v"
hello world
$ read a b c
1 2 3 4 5
$ echo "a=\'$a\' b=\'$b\' c=\'$c\'"
a='1' b='2' c='3 4 5'
```
read -n "Do you like learning Shell? 
read answer
# get first letter of answer converted to lower case
answer="$(
    echo "$answer"
    | cut -c1
    | tr A-Z a-z
)"
if test "$answer" = "y"
then
    response=":)"
elif test "$answer" = "n"
then
    response=":("
else
    response="??"
fi
echo "$response"
```

Source code for `read_response_if.sh`

```
#!/bin/dash
# written by andrewt@unsw.edu.au for COMP(2041|9044)
# over-simple /bin/cat emulation using read
# setting the special variable IFS to the empty string
# stops white space being stripped
for file in "$@"
    do
        while IFS= read -r line
            do
                echo "$line"
            done <$file
    done
```

Source code for `read_cat.sh`

```
```

**case statements - syntax**

```
case word in
    pattern1
        commands1
    ;;
    pattern2
        commands2
    ;;
    patternn
        commandsN
esac
```

- `word` is compared to each `pattern`, in turn.
- for the first `pattern` that matches
  the corresponding `commands`, is executed
  and the case statement finishes.
case statements in Shell

- case patterns use the same language as filename expansion (globbing)
  - In other words the special characters are `* ? []'
  - Patterns are not interpreted as regexes
- Shell programmer used to use `case' statements heavily for efficiency
  - Much less important now and many shell programmers don't use `case'
  - But use of `case' can still make shell code more readable

# Checking number of command line args
```bash
case $# in
  0) echo "You forgot to supply the argument" ;;
  1) filename=$1 ;;
  *) echo "You supplied too many arguments" ;;
esac
```

# Classifying a file via its name
```bash
case "$file" in
  *.c) echo "$file looks like a C source-code file" ;;
  *.h) echo "$file looks like a C header file" ;;
  *.o) echo "$file looks like an object file" ;;
  ?) echo "$file's name is too short to classify" ;;
  *) echo "I have no idea what $file is" ;;
esac
```

case - simple example

```bash
echo -n "Do you like learning Shell? 
read answer
case "$answer" in
  [Yy]*)
    response=":)"
  ;;
  [Nn]*)
    response=":("
  ;;
  *)
    response="??"
esac
echo "$response"
```

Source code for `read_response_case.sh`
creating a 1001 file C program - getting started

```c
#include <stdio.h>

int main(void) {
    int v = 0;
    printf("%d\n", v);
    return 0;
}
```

Creating the files:

```bash
cat >>main.c <<'eof'
int f$i(void); 
v += f$i();
eof
cat >file$i.c <<eof
int f$i(void) {
    return $i;
} 
eof

i=$((i + 1))
done
```

Compiling & Running the program:

```bash
cat >>main.c <<'eof'
printf("%d\n", v);
eof
```

```bash
time clang main.c file*.c
./a.out
```
shell functions

- shell functions have this form:

  ```bash
  name () {
    commands
  }
  ```

- function arguments passed in: `$@ $1 $2 ...`

- use `return` to stop function execution and return exit status
  - beware: `exit` in a function still terminates entire program

- `local` limit scope of variables to function
  - `local` is not POSIX, but is widely supported

example - shell function

```bash
#!/bin/dash
# written by andrewt@unsw.edu.au for COMP(2041|9044)
# demonstrate simple use of a shell function
repeat_message() {
  n=$1
  message=$2
  for i in $(seq 1 $n)
  do
    echo "$i: $message"
  done
}
repeat_message 3 "I love uniq"
repeat_message 1 "I love sort"
repeat_message 2 "I love grep"
```

source code for repeat_message.sh

example - local variables in a shell function

```bash
# print print numbers < 1000
# note use of local Shell builtin to scope a variable
# without the local declaration
# the variable i in the function would be global
# and would break the bottom while loop
# local is not (yet) POSIX but is widely supported
is_prime() {
  local n i
  n=$1
  i=2
  while test $i -lt $n
  do
    test $((n % i)) -eq 0 &&
    return 1
    i=$((i + 1))
  done
  return 0
}

for i in $(seq 1 1000)
do
  is_prime $i
  echo $i
done
```

source code for local.sh
shell functions

name () {
    commands
}
```

- function arguments passed in: `$@ $1 $2` ...
- use `return` to stop function execution and return exit status
  - beware: `exit` in a function still terminates entire program
- `local` limit scope of variables to function
  - `local` is not POSIX, but is widely supported

example - shell function

```
#!/bin/dash
# written by andrewt@unsw.edu.au for COMP(2041|9044)
# demonstrate simple use of a shell function
repeat_message() {
    n=$1
    message=$2
    for i in $(seq 1 $n)
    do
        echo "$i: $message"
    done
}
repeat_message 3 "I love uniq"
repeat_message 1 "I love sort"
repeat_message 2 "I love grep"
```

source code for repeat_message.sh

example - local variables in a shell function

```
# print print numbers < 1000
# note use of local Shell builtin to scope a variable
# without the local declaration
# the variable i in the function would be global
# and would break the bottom while loop
# local is not (yet) POSIX but is widely supported
is_prime() {
    local n i
    n=$1
    i=2
    while test $i -lt $n
    do
        test $((n % i)) -eq 0 &&
        return 1
        i=$((i + 1))
    done
    return 0
}

i=0
while test $i -lt 1000
do
    is_prime $i && echo $i
    i=$((i + 1))
done
```

source code for local.sh
example plagiarism detection - simple diff

```sh
# Note use of diff -iw so changes in white-space or case are ignored
for file1 in "@$"
do
  for file2 in "@$"
do
    test "$file1" = "$file2" &&
    break # avoid comparing pairs of assignments twice
  if
diff -iBw "$file1" "$file2" >/dev/null
  then
    echo "$file1 is a copy of $file2"
  fi
done
done
```

source code for plagiarism_detection.simple_diff.sh

plagiarism detection - ignoring changes to comments

```sh
# The substitution s///.*/// removes // style C comments.
# This means changes in comments won't affect comparisons.
# Note use of temporary files is insecure - an attacker can anticipate the filename
TMP_FILE1=/tmp/plagiarism_tmp1$$
TMP_FILE2=/tmp/plagiarism_tmp2$$
for file1 in "@$"
do
  for file2 in "@$"
do
    test "$file1" = "$file2" &&
    break # avoid comparing pairs of assignments twice
    sed 's///.*///' "$file1" >$TMP_FILE1
    sed 's///.*///' "$file2" >$TMP_FILE2
  if
diff -i -w $TMP_FILE1 $TMP_FILE2 >/dev/null
  then
    echo "$file1 is a copy of $file2"
  fi
done
done
rmd -f $TMP_FILE1 $TMP_FILE2
```

source code for plagiarism_detection.comments.sh

robust creation & removal of temporary files

- our code can be more robust and more secure
  by using mktemp to generate temporary file names
- we can also use the built-in shell `trap` command
  to ensure temporary files are removed however the script exits
- temporary file creation is major source of security holes
  be very careful creating temporary files
- in all languages, use existing robust & well-tested code such as `mktemp`
  - don't write your own code
- `mktemp` is not (yet) standardized by POSIX
  - simple uses are portable to many platforms
# change all C strings to the letter 's'
# and change all identifiers to the letter 'v'.
# Hence changes in strings & identifiers will be ignored.
TMP_FILE1=$(mktemp)
TMP_FILE2=$(mktemp)

# trap allows use to remove temporary files if program interrupted
trap 'rm -f $TMP_FILE1 $TMP_FILE2' EXIT

# s/"[^"]"/s/g changes strings to the letter 's'
# It won't match a few C strings which is OK for our purposes
# s/[a-zA-Z_][a-zA-Z0-9_]*/v/g changes variable names to 'v'
# It will also change function names, keywords etc. which is OK for our purposes.
transform() {
    sed 's///.*//
        s/"[^"]"/s/g
        s/[a-zA-Z_][a-zA-Z0-9_]*/v/g
        '$1'
}

source code for plagiarism_detection.identifiers.sh

for file1 in "@"
do
    for file2 in "@"
do
        test "$file1" = "$file2" &&
            break # avoid comparing pairs of assignments twice
        transform "$file1" >$TMP_FILE1
        transform "$file2" >$TMP_FILE2
        if diff -iBw $TMP_FILE1 $TMP_FILE2 >/dev/null
            then
                echo "$file1 is a copy of $file2"
        fi
    done
done

source code for plagiarism_detection.identifiers.sh

 TMP_FILE1=$(mktemp)
 TMP_FILE2=$(mktemp)
 trap 'rm -f $TMP_FILE1 $TMP_FILE2' EXIT
 # Note the use of sort so line reordering won't prevent detection of plagiarism.
 transform() {
     sed 's/\[//
         s/\[^\]\[/s/g
         s/[a-zA-Z_][a-zA-Z0-9_]*/v/g
         '$1'
     }

source code for plagiarism_detection.reordering.sh

plagiarism detection - ignoring changes in code order
Example - creating a temporary directory

```bash
# securely & robustly create a new temporary directory
temporary_directory=$(mktemp -d)
# ensure temporary directory + all its contents removed on exit
trap 'rm -rf "$temporary_directory"; exit' INT TERM EXIT
# change working directory to the new temporary directory
cd "$temporary_directory" || exit 1
# we are now in an empty directory
# and create any number of files & directories
# which all will be removed by the trap above
# e.g. create one thousand empty files
seq 1 1000 | xargs touch
# print current directory and list files
pwd
ls -l
```

Cryptographic hash function

- algorithm maps byte sequence of any length to certain number of bits
- e.g sha256 input: any number of bytes, output 256 bits (= 8 bytes) hash
- one way function - not feasible to reverse
- given a hash, not feasible to compute an input which produces that hash
- collisions (different inputs producing the same hash) occur but are vanishingly rare
- small change to input changes hash completely
- many applications:
  - hashes of passwords stored rather than password itself
  - integrity check on set of files
  - fingerprint a file

plagiarism detection - using hashing

```bash
# Improved version of plagiarism_detection.reordering.sh
# Note use sha256sum to calculate a Cryptographic hash of the modified file
# and use of sort && uniq to find files with the same hash
# This allows execution time linear in the number of files
# We could use a faster less secure hashing function instead of sha2
sha2hash() {
    sed 's/\ \//
    s/"[^"]*/s/g
    s/[a-zA-Z_][a-zA-Z0-9_]*//v/g
    ' $1
    sort
    sha256sum
}
for file in "$@"
do
echo "$(sha2hash $file) $file"
done| sort
uniq -w32 -d --all-repeated=separate
```
example - using a signal to provide a time limit

```bash
my_process_id=$$
# launch a asynchronous sub-shell that will kill
# this process in a second
(sleep 1; kill $my_process_id) &
i=0
while true
do
    echo $i
    i=$((i + 1))
done
```

source code for async.v0.sh

- **command &** executes command but does not wait for it to finish
- **sleep** suspends execution for a second
- **kill** sends a signal to a process, which by default causes it to exit

intercepting signals with trap

- **trap** specifies commands to be executed if a signal is received, e.g.:

```bash
# count slowly and laugh at interrupts (ctrl-C)
# catch signal SIGINT and print message
trap 'echo ha ha' INT
n=0
while true
do
    echo "$n"
    sleep 1
    n=$((n + 1))
done
```

source code for laugh.sh

- **trap** is useful for cleaning up temporary files before termination, e.g.

```bash
trap 'rm -f "$TMP_FILE"; exit' INT TERM EXIT
```

example - catching a signal with trap

```bash
# catch signal SIGTERM, print message and exit
trap 'echo loop executed $n times in 1 second; exit 0' TERM
# launch a sub-shell that will terminate
# this process in 1 second
my_process_id=$$
(sleep 1; kill $my_process_id) &
n=0
while true
do
    n=$((n + 1))
done
```

source code for async.v1.sh
# compile the files of a multi-file C program in parallel
# use create_1001_file_C_program.sh to create suitable test data
# On a CPU with n cores this can be (nearly) n times faster
# If there are large number of C files we
# may exhaust memory or operating system resources

```
for f in "$@
    do
