

COMP2521 (21T3)

Ass2 (part-1) : How to Implement?

Notes:

- The document offers some **suggestions only**, with incomplete pseudo code
- The pseudo code is easy to read, but may not be efficient. You need to improve it!
- You can use code from labs/lecture material, however, must acknowledge it and provide a reference. For example you can use graph ADT implementation from one of the labs, and adapt it for this assignment.
- You can build a graph structure using Adjacency Matrix or List Representation.

readData.c

List_of_Urls $\leftarrow$ GetCollection()

Create a set (list) of urls to process by reading data from file
“collection.txt”

Graph g $\leftarrow$ GetGraph(List_of_Urls)

Create empty graph (use graph ADT in say graph.h and graph.c)

For each url in the above list

- read <url>.txt file, and update graph by adding a node and outgoing links

pagerank.h

pagerank.c

pagerank.c

Get args : d, diffPR, maxIterations

List_of_Urls $\leftarrow$ GetCollection()

Graph g $\leftarrow$ GetGraph(List_of_Urls)

List_Urls_PageRanks = calculatePageRank(g, d, diffPR, maxIterations);

Ordered_List_Urls_PageRanks = order (List_Urls_PageRanks)

Output Ordered_List_Urls_PageRanks to “pagerankList.txt”

searchPagerank.h

searchPagerank.c

searchPagerank.c

Get query words from arguments

```
matched_Url_list ← findMatchedUrls("invertedIndex.txt", queryWords)  
matched_Urls_with_PR ← findPagerank("pagerankList.txt", matched_Url_list)
```

Output ordered urls on stdout

W^{out} : How to calculate?

$W_{(v,u)}^{out}$ is the weight of $link(v, u)$ calculated based on the number of outlinks of page u and the number of outlinks of all reference pages of page v .

$$W_{(v,u)}^{out} = \frac{O_u}{\sum_{p \in R(v)} O_p} \quad (6)$$

where O_u and O_p represent the number of outlinks of page u and page p , respectively. $R(v)$ denotes the reference page list of page v .

- ❖ **Reference pages** of url22 are url21, url31, url32 and url34
- ❖ **Ignore** self-loops (i.e. url21 to url21), and also parallel edges (if exist)

let's say we want to calculate wOut for a link from url22 to url21.

In example, **1** refers to url21, and out-degree of url21 is 1, **outDegree(url21) = 1**.

2 refers to url22. **Reference pages of page url22** are url21, url31, url32 and url34 (out links).

outDegree(url21) = 1, outDegree(url31) = 3, outDegree(32) = 0 and outDegree(34) = 0.

As per the specs, to avoid issues related to division by zero, out-degrees of 32 and 34 are considered to be **0.5**.

So, for the link url22 to url21, $wOut[2][1] = (1) / (1+3+0.5+0.5) = 0.20$ (same as in the log file).
