bfs and dfs
path checking
path finding

## Problems on Graphs

Common problems on graphs:

- Is there a path between two vertices?
- What is the shortest path between two vertices?
- Is the graph connected?
- If we remove an edge, is the graph still connected?
- Which vertices are reachable from a particular vertex?
- Is there a cycle that passes through all vertices?

All of the above problems can be solved by a systematic exploration of a graph via its edges.

This systematic exploration is called traversal or search.

Graph Traversa BFS and DFS

## PROBLEM

Is there a path between vertices $s r c$ and dest?

Possible approach:
(1) Examine vertices adjacent to $s r c$

2 If any of them is dest, we're done!
(3) Otherwise, check vertices two edges away from src
(4) Repeat looking further and further away from src

The above summarises one form of graph traversal.

Two primary methods for graph traversal/search:

## Breadth-first search (BFS)

- Prioritises visiting all neighbours over path-following
- "Go wide"
- Implemented iteratively (using a queue)

Depth-first search (DFS)

- Prioritises path-following over visiting all neighbours
- "Go deep"
- Implemented recursively or iteratively (using a stack)

## Graph Traversal

In what order would BFS and DFS visit the vertices of this graph?

# Graph Traversal 

Depth-first search

Breadth-first search visits vertices in order of distance from the starting vertex.

It visits the starting vertex, then the neighbours of the starting vertex, then the neighbours of those neighbours, etc.

BFS is implemented iteratively using a queue.

## Breadth-First Search

Data structures used in BFS:

- Visited array
- To keep track of which vertices have been visited
- Predecessor array
- To keep track of the predecessor of each vertex
- The predecessor of $v$ is the vertex from which we reached $v$
- i.e., the vertex before $v$ on the path to $v$
- Queue
- First-in-first-out data structure
- Stores unvisited vertices in the order that they should be visited

# Breadth-First Search 

Algorithm:
(1) Create/initialise data structures:

- Create visited array, initialised to false
- Create predecessor array, initialised to -1
- Create empty queue
(2) Mark starting vertex as visited and enqueue it
(3) While the queue is not empty:
(1) Dequeue a vertex
- Let this vertex be $v$
(2) Explore $v$ - that is, for each of $v$ 's unvisited neighbours:
(1) Mark it as visited
(2) Set its predecessor to $v$
(3) Enqueue it

## queue

|  | [0] | [1] | [2] | [3] | [4] | [5] | [6] | [7] | [8] |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| visited | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| pred | -1 | 0 | 0 | 2 | 5 | 0 | 5 | 5 | 4 | 7 |
| queue $\begin{array}{llllllllll}0 & 1 & 2 & 5 & 3 & 4 & 6 & 7 & 8 & 9\end{array}$ |  |  |  |  |  |  |  |  |  |  |

# Breadth-First Search 

## Graph

 Traversal
## BFS

bfs ( $G, s r c$ ):
Input: graph $G$, starting vertex src
create visited array, initialised to false
create predecessor array, initialised to -1 create queue $Q$
visited[src] = true enqueue $s r c$ into $Q$
while $Q$ is not empty:
$v=$ dequeue from $Q$
for each neighbour $w$ of $v$ in $G$ where visited $[w]=$ false:
visited $[w]=$ true
predecessor $[w]=v$
enqueue $w$ into $Q$

# Breadth-First Search 

When using a predecessor array in BFS, the predecessor array can double as a visited array predecessor $[v]=-1$ means $v$ is not visited

# Breadth-First Search 

## Graph

 Traversalbfs( $G$, src):
Input: graph $G$, starting vertex src
create predecessor array, initialised to -1 create queue $Q$
predecessor[src] = src // <- mark src as visited enqueue src into $Q$
while $Q$ is not empty:
$v=$ dequeue from $Q$
for each neighbour $w$ of $v$ in $G$ where predecessor $[w]=-1$ :
predecessor $[w]=v$ enqueue $w$ into $Q$

# Breadth-First Search 

BFS is $O(V+E)$ when using the adjacency list representation:

- Typical queue implementation has $O(1)$ enqueue and dequeue
- Each vertex is visited at most once $\Rightarrow O(V)$
- For each vertex, all of its edges are considered once $\Rightarrow O(E)$

A BFS finds the shortest path between the starting vertex and all other vertices.

- Shortest path in terms of the number of edges

The shortest path between src and dest can be found by tracing backwards through the predecessor array (from dest to src).

## Example: Shortest path from 0 to 8

## Example: Shortest path from 0 to 8

## Example: Shortest path from 0 to 8

## Example: Shortest path from 0 to 8

## Example: Shortest path from 0 to 8

## Example: Shortest path from 0 to 8

## Example: Shortest path from 0 to 8

$$
0 \longrightarrow 5 \rightarrow 4 \rightarrow 8
$$

## Graph

 Traversal```
bfsFindPath(G, src, dest):
    Input: graph G, vertices src and dest
    ... BFS starting from src ...
    if predecessor[dest] }\not=-1
        v = dest
        while v \not= src:
            print v, "<-"
            v = predecessor[v]
        print src
```

Depth-first search goes as far down one path
as possible until it reaches a dead end, then backtracks until it finds a new path to take, then repeats

DFS can be implemented recursively or iteratively.

Depth-first search is described recursively as:
(1) Mark current vertex as visited

- The first time, this is the starting vertex

2 For each neighbour of the current vertex:

- If it has not been visited:
- Recursively traverse starting from that vertex

The recursion naturally induces backtracking.

# Recursive Depth-First Search 

```
dfs(G,src):
    Input: graph G, starting vertex src
    create visited array, initialised to false
    dfsRec(G, src, visited)
dfsRec(G, v, visited):
    Input: graph G, vertex v, visited array
    visited[v] = true // "visit" v
    for each neighbour w of v in G:
        if visited[w] = false:
            dfsRec(G, w, visited)
```

Recursive Depth-First Search
Example

DFS starting at 0

|  | [0] | [1] | [2] | [3] | [4] | [5] | [6] | [7] | [8] | [9] |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| visited | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

visit order

Recursive Depth-First Search
Example

## Graph

 TraversalDone

|  | [0] | [1] | [2] | [3] | [4] | [5] | [6] | [7] | [8] | ] |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| visited | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

[^0]
# Recursive Depth-First Search 

Recursive DFS is $O(V+E)$ when using the adjacency list representation:

- Each vertex is visited at most once $\Rightarrow O(V)$
- Function is called on each vertex at most once
- For each vertex, all of its edges are considered once $\Rightarrow O(E)$

Recursive DFS can be adapted to check if a path exists between two vertices. Idea:

- To check if a path exists between src and dest:
- If $s r c=d e s t$, then there is a path (the empty path)
- Otherwise, for each neighbour of $s r c$, recursively check if there is a path from that neighbour to dest

# Path-Checking with Recursive DFS 

Does there exist a path between 0 and 7 in this graph?

# Path-Checking with Recursive DFS 

## Answer: Yes

## Path－Checking with Recursive DFS

## Graph

 Traversal```
dfsHasPath(G, src, dest):
```

dfsHasPath(G, src, dest):
Input: graph G, vertices src and dest
Input: graph G, vertices src and dest
Output: true if there is a path from src to dest
Output: true if there is a path from src to dest
false otherwise
false otherwise
create visited array, initialised to false
create visited array, initialised to false
return dfsHasPathRec(G, src, dest, visited)
return dfsHasPathRec(G, src, dest, visited)
dfsHasPathRec(G, v, dest, visited):
dfsHasPathRec(G, v, dest, visited):
Input: graph G, vertices v and dest, visited array
Input: graph G, vertices v and dest, visited array
visited[v] = true
visited[v] = true
if v=dest:
if v=dest:
return true
return true
for each neighbour w of v in G:
for each neighbour w of v in G:
if visited[w] = false:
if visited[w] = false:
if dfsHasPathRec(G, w, dest, visited):
if dfsHasPathRec(G, w, dest, visited):
return true
return true
return false

```

\title{
Path-Checking with Recursive DFS
}
\(O(V+E)\) when using the adjacency list representation:
- Algorithm is just a modified recursive DFS with return statements

Knowing whether a path exists can be useful．
Knowing what the path is can be even more useful．
Idea：
－Record the predecessor of each vertex during the DFS
－Trace backwards through the path after the DFS

\title{
Path-Finding with Recursive DFS
}

\section*{Graph} Traversal
```

dfsFindPath(G, src, dest):
Input: graph G, vertices src and dest
create predecessor array, initialised to -1
predecessor[src] = src
if dfsFindPathRec(G, src, dest, predecessor):
v = dest
while v \not= src:
print v, "<-"
v = predecessor[v]
print src

```

\title{
Path-Finding with Recursive DFS
}
```

dfsFindPathRec(G, v, dest, predecessor):
if v=dest:
return true
for each neighbour w of v in G:
if predecessor[w] = -1:
predecessor[w] = v
if dfsFindPathRec(G, w, dest, predecessor):
return true

```
    return false

Find a path from 0 to 7

\section*{Path-Finding with Recursive DFS}

\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|}
\hline & [0] & [1] & [2] & [3] & [4] & [5] & [6] & [7] & [8] & [9] \\
\hline pred & 0 & 0 & 3 & 5 & 3 & 1 & -1 & 4 & -1 & -1 \\
\hline
\end{tabular}

Clearly, DFS is not guaranteed to find the shortest path.

DFS can be implemented iteratively.
Iterative DFS is similar to BFS, but there are a few crucial differences:
- DFS uses a stack instead of a queue
- DFS marks a vertex as visited after removing it from the stack, not when adding it (which is what BFS does, but with a queue)

\section*{Iterative Depth-First Search}

\section*{Graph} Traversal
\[
\mathrm{dfs}(G, s r c):
\]
```

        Input: graph G, vertex src
    ```
    create visited array, initialised to false
    create predecessor array, initialised to -1
    create stack \(S\)
    push src onto \(S\)
    while \(S\) is not empty:
        \(v=\) pop from \(S\)
        if visited[v] = true:
            continue // i.e., return to start of loop
            visited[ \(v\) ] = true

            predecessor \([w]=v\)
            push \(w\) onto \(S\)

\title{
Iterative Depth-First Search
}

Iterative DFS is \(O(V+E)\) when using the adjacency list representation.
- Typical stack implementation has \(O(1)\) push and pop
- Each vertex visited at most once \(\Rightarrow O(V)\)
- For each vertex, all of its edges are considered \(\Rightarrow O(E)\)

The edges traversed in a graph traversal form a spanning tree.
Consider the following graph:

A traversal starting at vertex 'a' forms the following spanning trees:

Breadth-first search

Depth-first search

If a graph is not connected, a graph traversal starting from a given vertex will not traverse the entire graph

\section*{Disconnected Graphs}

Solution
After initial traversal is complete, perform traversal again on an unvisited vertex, repeat until all vertices are visited

This produces a spanning forest

\(\operatorname{dfs}(G):\)
Input: graph \(G\)
create predecessor array, initialised to -1
for each vertex \(v\) in \(G\) :
if predecessor \([v]=-1\) :
dfsRec \((G, v\), predecessor)
...
https://forms.office.com/r/5c0fb4tvMb
