Sorting Algorithms (IV)

Non-Comparison-Based Sorting Algorithms

Sim Mautner

cs2521@cse.unsw.edu.au

$n \log n$ lower bound
radix sort

All of the sorting algorithms so far have been
comparison-based sorts.

It can be shown that these algorithms require $\Omega(n \log n)$ comparisons.
That is, they require at least $kn \log n$ comparisons for some constant k .

Why?

Suppose we need to sort 3 items.

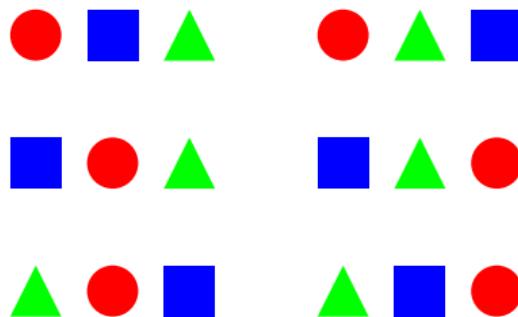

Obviously, one comparison is not sufficient to sort them.

Suppose we need to sort 3 items.

Even two comparisons are not sufficient to sort them. Why?

If we have 3 items, there are $3! = 6$ ways to order them:

Assuming items are unique, one of these permutations is in sorted order.

$n \log n$ Lower
Bound

Radix Sort

Suppose we performed the following comparisons:

Four combinations of results are possible:

(true, true), (true, false), (false, true), (false, false)

The two comparisons create four groups, and each permutation of items belongs to one of these groups

	true	true	false	false
	true	false	true	false

Mathematically,

If we have 3 items, then there are $3! = 6$ ways to order them.
In other words, 6 possible permutations.

But if we only perform 2 comparisons, then there are only $2^2 = 4$ groups,
so at least one group will contain more than one permutation.

We need at least 3 comparisons, because this creates $2^3 = 8$ groups,
so each permutation can belong in its own group.

If we have n items, then there are $n!$ permutations.

If we perform k comparisons, that creates up to 2^k groups.

So given n items, we must perform enough comparisons k such that

$$2^k \geq n!$$

So given n items, we must perform enough comparisons k such that

$$2^k \geq n!$$

Taking the \log_2 of both sides gives

$$\log_2 2^k \geq \log_2 n!$$

Since $\log_2 2^k = k$, we get

$$k \geq \log_2 n!$$

Using Stirling's approximation, we get

$$k \geq n \log_2 n - n \log_2 e + O(\log_2 n)$$

Removing lower-order terms gives

$$k = \Omega(n \log_2 n)$$

$n \log n$ Lower
Bound

Radix Sort

Therefore:

The theoretical lower bound on
worst-case execution time
for comparison-based sorts is $\Omega(n \log n)$.

$n \log n$ Lower Bound

Radix Sort

If we aren't limited to just comparing keys,
we can achieve better than $O(n \log n)$ worst-case time.

Non-comparison-based sorting algorithms exploit specific properties
of the data to sort it.

$n \log n$ Lower Bound

Radix Sort

Pseudocode
Example
Analysis
Properties

Radix sort is a non-comparison-based sorting algorithm.

It requires us to be able to decompose our keys into individual symbols (digits, characters, bits, etc.), for example:

- The key 372 is decomposed into (3, 7, 2)
- The key “sydney” is decomposed into ('s', 'y', 'd', 'n', 'e', 'y')

Formally, each key k is decomposed into a tuple $(k_1, k_2, k_3, \dots, k_m)$.

$n \log n$ Lower Bound

Radix Sort

Pseudocode

Example

Analysis

Properties

Ideally, the range of possible symbols is reasonably small, for example:

- Numeric: 0-9
- Alphabetic: a-z

The number of possible symbols is known as the **radix**, and is denoted by R .

- Numeric: $R = 10$ (for base 10)
- Alphabetic: $R = 26$

If the keys have different lengths, pad them with a suitable symbol, for example:

- Numeric: 123, 015, 007
- Alphabetic: “abc”, “zz ”, “t u”

$n \log n$ Lower Bound

Radix Sort

Pseudocode

Example

Analysis

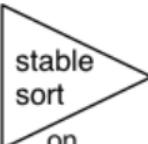

Properties

Method:

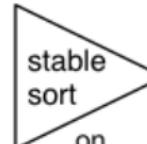

- Perform stable sort on k_m
- Perform stable sort on k_{m-1}
- ...
- Perform stable sort on k_1

Example:

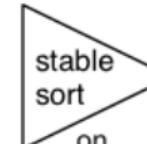

cat
ace
dog
cog
key
buy

stable sort
on third char

ace
dog
cog
cat
key
buy

stable sort
on second char

cat
ace
key
dog
cog
buy

stable sort
on first char

ace
buy
cat
cog
dog
key

Properties

```
radixSort(A):
    Input: array A of keys where
            each key consists of m symbols from an "alphabet"

    initialise R buckets // one for each symbol

    for i from m down to 1:
        empty all buckets
        for each key in A:
            append key to bucket key[i]

    clear A
    for each bucket (in order):
        for each key in bucket:
            append key to A
```

$n \log n$ Lower Bound

Example

Analysis

Properties

Assume alphabet is {‘a’, ‘b’, ‘c’}, so $R = 3$.

We want to sort the array:

[“abc”, “cab”, “baa”, “a”, “ca”]

First, pad keys with blank characters:

[“abc”, “cab”, “baa”, “a ”, “ca ”]

Each key contains three characters, so $m = 3$.

Radix Sort

Pseudocode

Example

Analysis

Properties

Analysis:

- Array contains n keys
- Each key contains m symbols
- Radix sort uses R buckets
- A single stable sort runs in time $O(n + R)$
- Radix sort uses stable sort m times

Hence, time complexity for radix sort is $O(m(n + R))$.

- $\approx O(mn)$, assuming R is small

Therefore, radix sort performs better than comparison-based sorting algorithms:

- When keys are short (i.e., m is small) and arrays are large (i.e., n is large)

$n \log n$ Lower Bound

Radix Sort

Pseudocode
