Minimum Spanning Trees

COMP2521 25T2

Kruskal's Algorithm

Prim's Algorithm

Comparison

Other Algorithm:

Appendix

A spanning tree of an undirected graph *G* is a subgraph of *G* that contains all vertices of *G*, that is connected and contains no cycles

A minimum spanning tree of an undirected weighted graph G is a spanning tree of G that has minimum total edge weight among all spanning trees of G

Applications: Electrical grids, networks Any situation where we want to connect nodes as cheaply as possible

◆□▶ ◆□▶ ◆ □ ▶ ◆ □ ▶ ● □ ● ● ● ●

Proof by exchange argument.

Idea:

- Suppose there exists another algorithm A which makes a different set of choices
 - In this case, chooses a different set of edges for the MST
 - Identify one choice made by A which is not made by our algorithm
 - Show that by exchanging that choice with one of the choices made by our algorithm, the solution does not become worse or less optimal
 - In this case, the "solution" is the spanning tree produced
 - In this case, an "optimal" solution is a spanning tree that costs as little as possible

Now A' is once again a spanning tree, but it is more similar to K than A and it costs no more than A.

Kruskal's Algorithm Analysis - Correctness

Minimum Spanning Trees

Kruskal's Algorithm Example Pseudocode Analysis Correctness Time complexity

Prim's Algorithm

Comparison

Other Algorithms Appendix

Now A' is once again a spanning tree, but it is more similar to K than A and it costs no more than A.

Repeat until A' is identical to K. Each time we perform an exchange, the spanning tree does not increase in cost.

Therefore, *K* is an optimal spanning tree (MST).

Kruskal's Algorithm Example Pseudocode Analysis Correctness Time complexity

Prim's Algorithm

Comparison

Other Algorithms

Appendix

Analysis:

- Sorting edges is $O(E \cdot \log E)$
- Main loop has at most *E* iterations
- Different ways to check if adding an edge would form a cycle
 - Cycle/path checking is O(V) in the worst case (adjacency list) \Rightarrow overall cost = $O(E \cdot \log E + E \cdot V) = O(E \cdot V)$
 - Using union-find data structure is close to O(1) in the worst case \Rightarrow overall cost = $O(E \cdot \log E + E) = O(E \cdot \log E) = O(E \cdot \log V)$
