Processes and Threads

Learning Outcomes

 An understanding of fundamental concepts of processes and threads

Major Requirements of an Operating System

- Interleave the execution of several processes to maximize processor utilization while providing reasonable response time
- Allocate resources to processes
- Support interprocess communication and user creation of processes

Processes and Threads

- Processes:
 - Also called a task or job
 - Execution of an individual program
 - "Owner" of resources allocated for program execution
 - Encompasses one or more threads
- Threads:
 - Unit of execution
 - Can be traced
 - list the sequence of instructions that execute
 - Belongs to a process

Figure 3.1 Snapshot of Example Execution (Figure 3 at Instruction Cycle 13

.....

100 = Starting address of dispatcher program

shaded areas indicate execution of dispatcher process; first and third columns count instruction cycles; second and fourth columns show address of instruction being executed

Figure 3.3 Combined Trace of Processes of Figure 3.1

Summary: The Process Model

- Multiprogramming of four programs
- Conceptual model of 4 independent, sequential processes (with a single thread each)
- Only one program active at any instant

Figure 4.1 Threads and Processes [ANDE97]

Process and thread models of selected OSes

- Single process, single thread
 - MSDOS
- Single process, multiple threads
 - OS/161 as distributed
- Multiple processes, single thread
 - Traditional unix
- Multiple processes, multiple threads
 - Modern Unix (Linux, Solaris), Windows 2000
- Note: Literature (incl. Textbooks) often do not cleanly distinguish between processes and threads (for historical reasons)

Process Creation

Principal events that cause process creation

- 1. System initialization
 - Foreground processes (interactive programs)
 - Background processes
 - Email server, web server, print server, etc.
 - Called a *daemon* (unix) or *service* (Windows)
- 2. Execution of a process creation system call by a running process
 - New login shell for an incoming telnet/ssh connection
- 3. User request to create a new process
- 4. Initiation of a batch job
- Note: Technically, all these cases use the same system mechanism to create new processes.

Process Termination

Conditions which terminate processes

- 1. Normal exit (voluntary)
- 2. Error exit (voluntary)
- 3. Fatal error (involuntary)
- 4. Killed by another process (involuntary)

Process/Thread States

- 1. Process blocks for input
- 2. Scheduler picks another process
- 3. Scheduler picks this process
- 4. Input becomes available

- Possible process/thread states
 - running
 - blocked
 - ready
- Transitions between states shown
 The UNIVERSITY OF
 New SOUTH WALES

Some Transition Causing Events

Running >Ready

- Voluntary Yield()
- End of timeslice

Running >Blocked

- Waiting for input
 - File, network,
- Waiting for a timer (alarm signal)
- Waiting for a resource to become available

Dispatcher

- Sometimes also called the scheduler
 - The literature is also a little inconsistent on this point
- Has to choose a *Ready* process to run
 - How?
 - It is inefficient to search through all processes

The Ready Queue

(b) Queuing diagram

What about blocked processes?

 When an *unblocking* event occurs, we also wish to avoid scanning all processes to select one to make *Ready*

Using Two Queues

Implementation of Processes

- A processes' information is stored in a process control block (PCB)
- The PCBs form a process table
 - Sometimes the kernel stack for each process is in the PCB
 - Sometimes some process info is on the kernel stack
 - E.g. registers in the *trapframe* in OS/161
 - Reality is much more complex (hashing, chaining, allocation bitmaps,...)

Implementation of Processes

| Process management | Memory management | File management |
|---------------------------|--------------------------|-------------------|
| Registers | Pointer to text segment | Root directory |
| Program counter | Pointer to data segment | Working directory |
| Program status word | Pointer to stack segment | File descriptors |
| Stack pointer | | User ID |
| Process state | | Group ID |
| Priority | | |
| Scheduling parameters | | |
| Process ID | | |
| Parent process | | |
| Process group | | |
| Signals | | |
| Time when process started | | |
| CPU time used | | |
| Children's CPU time | | |
| Time of next alarm | | |

Example fields of a process table entry

Threads The Thread Model

(a) Three processes each with one thread
 (b) One process with three threads
 THE UNIVERSITY OF NEW SOUTH WALES

The Thread Model

| Per process items | Per thread items |
|-----------------------------|------------------|
| Address space | Program counter |
| Global variables | Registers |
| Open files | Stack |
| Child processes | State |
| Pending alarms | |
| Signals and signal handlers | |
| Accounting information | |

- Items shared by all threads in a process
- Items private to each thread

Threads Analogy

The Hamburger Restaurant

Single-Threaded Restaurant

Multithreaded Restaurant

26

Finite-State Machine Model (Event-based model)

The Thread Model

Each thread has its own stack

Thread Model

- Local variables are per thread
 - Allocated on the stack
- Global variables are shared between all threads
 - Allocated in data section
 - Concurrency control is an issue
- Dynamically allocated memory (malloc) can be global or local
 - Program defined (the pointer can be global or local)

A word processor with three threads

A multithreaded Web server

Thread Usage

```
while (TRUE) {
  get_next_request(&buf);
  handoff_work(&buf);
}
(a)
while (TRUE) {
  wait_for_work(&buf)
  look_for_page_in_cache(&buf, &page);
  if (page_not_in_cache(&page)
      read_page_from_disk(&buf, &page);
  return_page(&page);
  }
  (b)
```

- Rough outline of code for previous slide
 (a) Dispatcher thread
 - (b) Worker thread can overlap disk I/O with execution of other threads

Thread Usage

| Model | Characteristics |
|-------------------------|---|
| Threads | Parallelism, blocking system calls |
| Single-threaded process | No parallelism, blocking system calls |
| Finite-state machine | Parallelism, nonblocking system calls, interrupts |

Three ways to construct a server

Summarising "Why Threads?"

- Simpler to program than a state machine
- Less resources are associated with them than a complete process
 - Cheaper to create and destroy
 - Shares resources (especially memory) between them
- Performance: Threads waiting for I/O can be overlapped with computing threads
 - Note if all threads are *compute bound*, then there is no performance improvement (on a uniprocessor)
- Threads can take advantage of the parallelism available on machines with more than one CPU (multiprocessor)
