XML and Databases

Lecture 8

Streaming Evaluation: how much memory do you need?

Sebastian Maneth NICTA and UNSW

CSE@UNSW -- Semester 1, 2010

Can you give an expression that returns the last / first occurrence of each distinct price element?

		
<price>3</price>		
<price>1</price> <price>3</price>	Should return	Should return
<price>1</price> <price>3</price> <price>4</price> <price>1</price> <price>1</price> <price>7</price>	<price>3</price> <price>4</price> <price>1</price> <price>7</price>	<price>3</price> <price>1</price> <price>4</price> <price>7</price>

Can you give an expression that returns the last / first occurrence of each distinct price element?

Should return	Should return
<price>3</price> <price>4</price> <price>1</price> <price>7</price>	<pri><price>3</price> <price>1</price> <price>4</price> <price>7</price></pri>
	<price>3</price> <price>4</price> <price>1</price>

What's the result for this query: /descendant::price[.=preceding::price][2]

Can you give an expression that returns the last / first occurrence of each distinct price element?

		
<price>3.0</price>		
<pre><price>1</price></pre>	Should return	Should return
<price>3.00</price>		
<price>1</price>	<price>3</price>	<pri><price>3.0</price></pri>
<price>3</price>	<pri><price>4</price></pri>	<price>1</price>
<pri><price>4</price></pri>	<pri><price>1.000</price></pri>	<price>4</price>
<pri><price>1.000</price></pri>	<price>7</price>	<price>7</price>
<pri><price>7</price></pri>		
70/		

What if we mean *number-distinctness* (not strings)?

Can you give an expression that returns the smallest (last) price element?

Can you give an expression that returns the smallest (last) price element?

Recall

- → Koch's CVT-algorithm for full XPath 1.0
- → Evaluation of Simple Paths //a/b/c
- → Arbitrary Queries over //, /, *

Outline

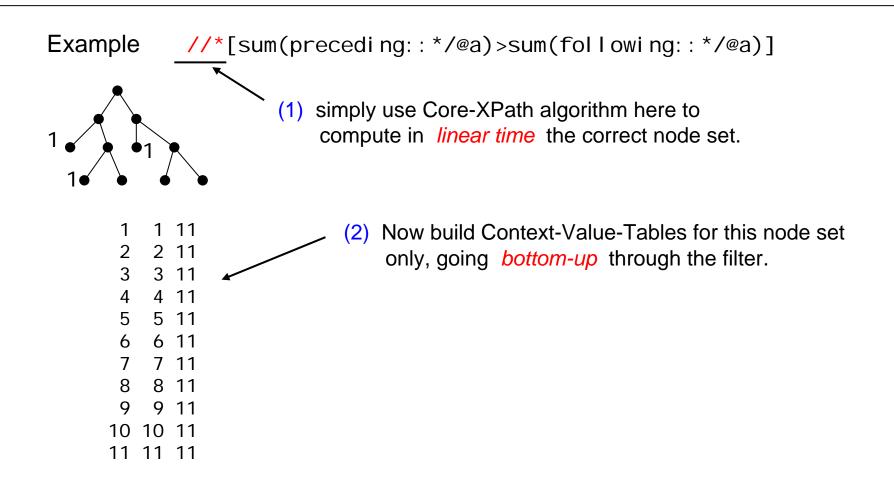

- 1. Automaton Approach
- 2. Parallel Evaluation of Multiple Queries
- 3. Sizes of Automata
- 4. How to deal with Filters
- 5. Existing Systems for Streaming XPath Evaluation

Recall: Koch's CVT-algorithm for full XPath 1.0

Question Which subsets of nodes need to appear in the CVTs?

Answer

(1) Compute *top-down* for filter-less query-part the exact node set, until a filter appears. (2) Build CVT (*bu*) for the respective sets.

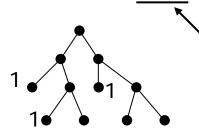

Recall: Koch's CVT-algorithm for full XPath 1.0

Question Which subsets of nodes need to appear in the CVTs?

Answer

(1) Compute *top-down* for filter-less query-part the exact node set, until a filter appears. (2) Build CVT (*bu*) for the respective sets.

Example //*[sum(preceding::*/@a)>sum(following::*/@a)]

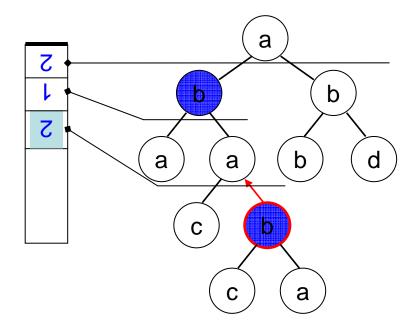

(1) simply use Core-XPath algorithm here to compute in *linear time* the correct node set.

Context-Value Tables

1	1 11	_	_	_	_	_	_	fal se
2	2 11	_	7-11	_	8. a	-	1	fal se
3	3 11	-	4-11	-	5. a, 8. a	-	2	fal se
4	4 11	3	7-11	3. a	8. a	1	1	fal se
5	5 11	3	6-11	3. a	8. a	1	1	fal se
6	6 11	3, 5	7-11	3. a, 5. a	8. a	2	1	true
7	7 11	2-6	-	3. a, 5. a	-	2	0	true
8	8 11	2-6	9-11	3. a, 5. a	_	2	0	true
9	9 11	2-6, 8	_	3. a, 5. a, 8. a	_	3	0	true
10	10 11	2-6, 8	11	3. a, 5. a, 8. a	_	3	0	true
11	11 11	2-6, 8, 10	-	3. a, 5. a, 8. a	_	3	0	true

→ evaluate in *one single pre-order traversal* (using a **stack)**

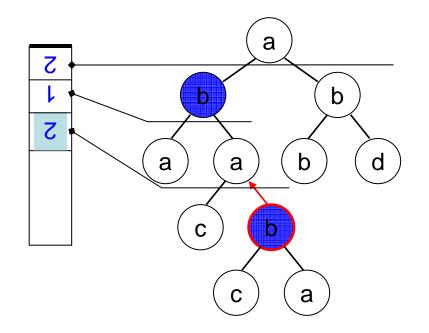

[endElement(b)] p = pop() = 2

```
//a/b =0
1
2
query match position: p = 2
```

```
[startElement( a )]
[startElement( b )]
[endElement( a )]
[startElement( a )]
[startElement( a )]
[startElement( c )]
[endElement( c )]
[startElement( b )]
[startElement( c )]
[startElement( c )]
[endElement( c )]
[startElement( a )]
[endElement( a )]
[endElement( a )]
[endElement( a )]
[endElement( a )]
```

→ evaluate in *one single pre-order traversal* (using a **stack)**

query match position: p = 2

Streaming Algorithm!

→ No need to store the document!!

Can evaluate on SAX event stream.

Simple Path //a_1/a_2/a_3/ . . . /a_n

TIME SPACE one pass through document tree.

stack of query positions.

height is bounded by depth of document tree.

BUT

Need **output buffers**, if subtrees of match nodes should be printed!

→ evaluate in *one single pre-order traversal* (using a **stack)**

If we print **node-IDs**, then no output buffers are needed!

query match position: p = 2

→ True Streaming, with memory need proportional to height.

Streaming Algorithm!

→ No need to store the document!!
Can evaluate on SAX event stream.

TIME one pass through document tree.

SPACE stack of query positions.

height is bounded by depth of document tree.

BUT

Need **output buffers**, if subtrees of match nodes should be printed!

2

→ evaluate in *one single pre-order traversal* (using a **stack)**

If we print **node-IDs**, then no output buffers are needed!

→ any good implementation of this algorithm should work for documents with depth up to a couple of millions, and

NO restriction on document size!

query match position: p = 2

Streaming Algorithm!

→ No need to store the document!!

Can evaluate on SAX event stream.

TIME one pass through document tree.

SPACE stack of query positions.

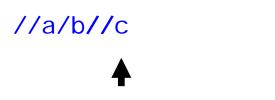

height is bounded by depth of document tree.

1 Byte/pos is enough for small queries!

→ evaluate in *one single pre-order traversal* (using a **stack)**

Arbitrary queries with /, //, *

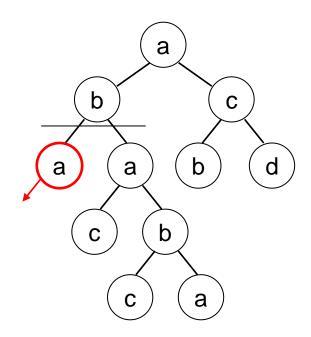

multiple //'s

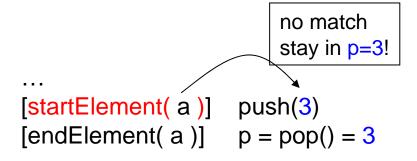

2

3

query match position: p = 3

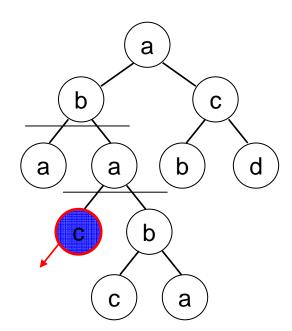

→ evaluate in one single pre-order traversal (using a stack)

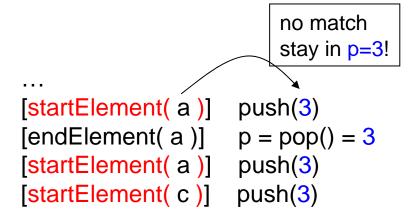

Arbitrary queries with /, //, *

//a/b//c

multiple //'s

query match position: p = 3

Result node!

Mark it, and stay in p=3.

→ evaluate in *one single pre-order traversal* (using a **stack**) Arbitrary queries with /, //, * //a/b//c 2 multiple //'s query match position: p = 3no match a stay in p=3!C [startElement(a)] push(3) [endElement(a)] p = pop() = 3b [startElement(a)] push(3) a [startElement(c)] push(3) Result node! Mark it, and stay in p=3. Output Node-ID Start copying to Output Buffer

→ evaluate in *one single pre-order traversal* (using a **stack)** Arbitrary queries with /, //, * //a/b//c 3 2 multiple //'s query match position: p = 3no match a stay in p=3!C [startElement(a)] push(3) [endElement(a)] p = pop() = 3b [startElement(a)] push(3) a [startElement(c)] push(3) [endElement(c)] p = pop() = 3[startElement(b)] push(3) [startElement(c)] push(3)

→ evaluate in *one single pre-order traversal* (using a **stack)** Arbitrary queries with /, //, * //a/b//c 2 multiple //'s query match position: p = 3a Stay at position 3, C for the complete subtree! b Never go back to pos. 1 or pos. 2!

→ evaluate in *one single pre-order traversal* (using a **stack)**

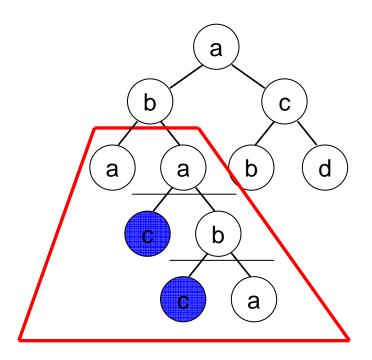

Arbitrary queries with /, //, *

multiple //'s

//a/b//c

query match position: p = 3

Optimizations (for Output Buffers)

- (1) If *inside a matched subtree*, record position (or range within buffer), instead of creating a new output buffer.
- (2) If *subtree is finished* (we are not inside a match), then we can write its buffer out and can start with empty buffer again.

[Worst Case:

root node selected. size of doc. Needed.]

2

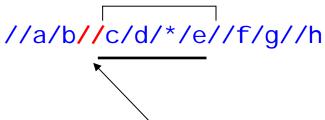

→ evaluate in one single pre-order traversal (using a stack)

Arbitrary queries with /, //, *

//a/b//c

multiple //'s

query match position: p = 3

→ Same as before

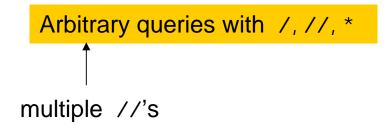

jump back within /-sequence.

AT MOST to the beginning of the last //.

Use KMP within /-sequence.

For *'s: build several KMP-tables.

→ evaluate in *one single pre-order traversal* (using a **stack)**

//a/b//c

query match position: p = 3

//a/b<mark>//</mark>c/d/*/e//f/g//h

Query Problem is solved!

Leave optimizations of

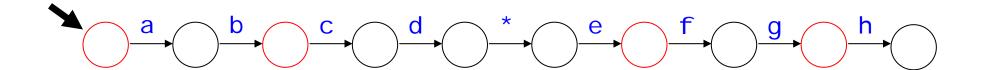

To OS/UNIX hackers.. ©

If Node-IDs are printed, then no output buffers are needed.

2

Then:

Memory proportional to height. Should run for arbitrary large docs!

//a/b//c/d/*/e//f/g//h

→ Same as before

jump back within /-sequence.

AT MOST to the beginning of the last //.

Use KMP within /-sequence.

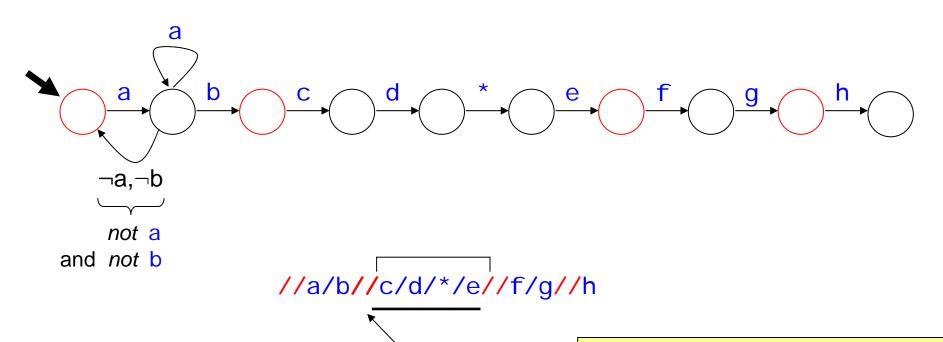

For *'s: build several KMP-tables.

Recall

Deterministic Automaton runs in

- → linear time and
- → constant space

(plus stack of states, if we run on paths of a tree)

→ Same as before

jump back within /-sequence.

AT MOST to the beginning of the last //.

Use KMP within /-sequence.

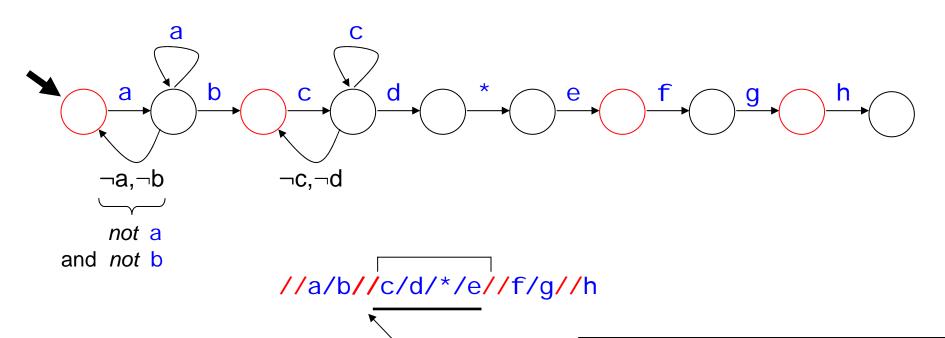

For *'s: build several KMP-tables.

Recall

Deterministic Automaton runs in

- 2. How many transitions are missing?

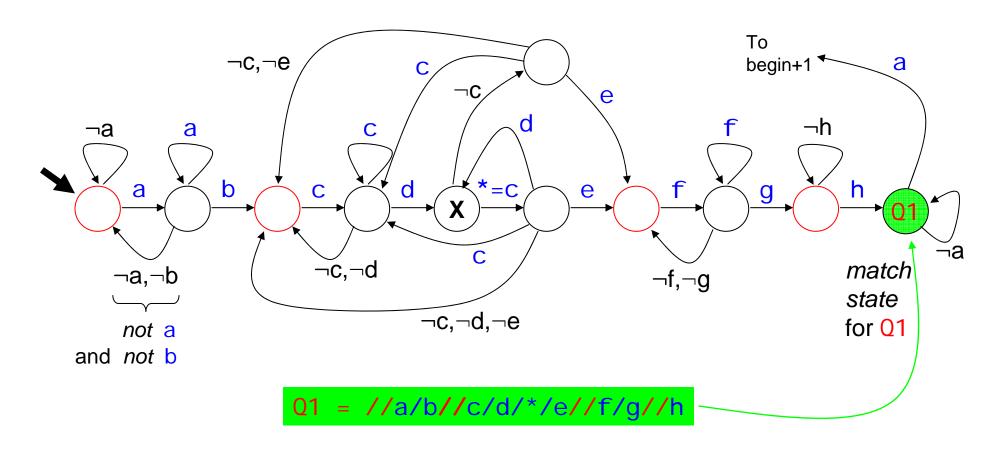

→ can be combined to evaluate MANY queries "in parallel".

ONE look-up per node!

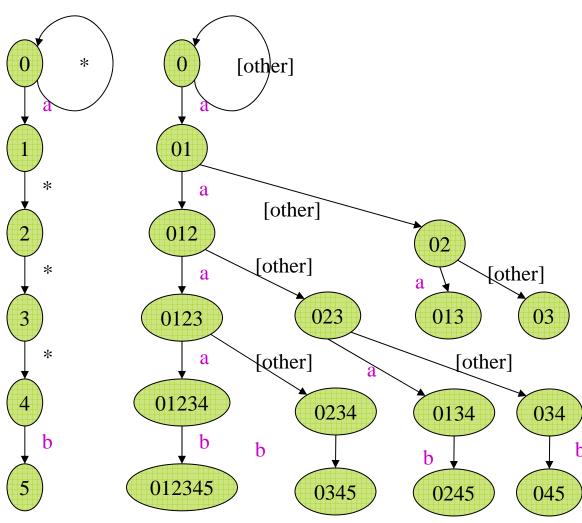

Combined automaton: $SIZE \leq SIZE(A1) \times SIZE(A2)$

3. The Size of the DFA

//a/*/*/*/b

Size of DFA = exponential in *'s

(not a real concern)

NFA

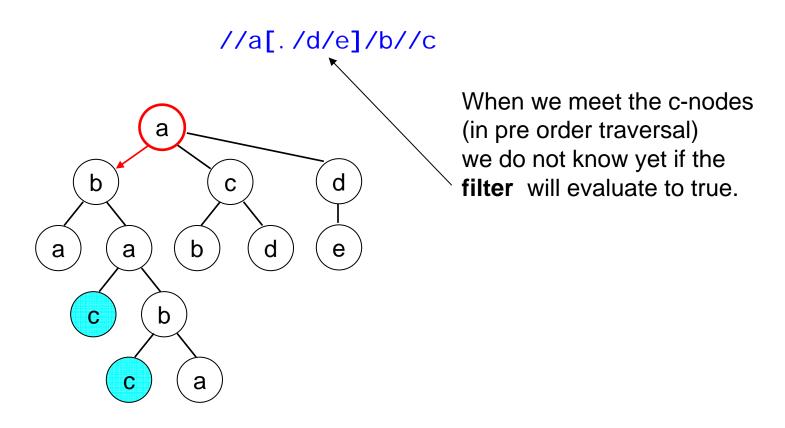

DFA (fragment, and without back edges)

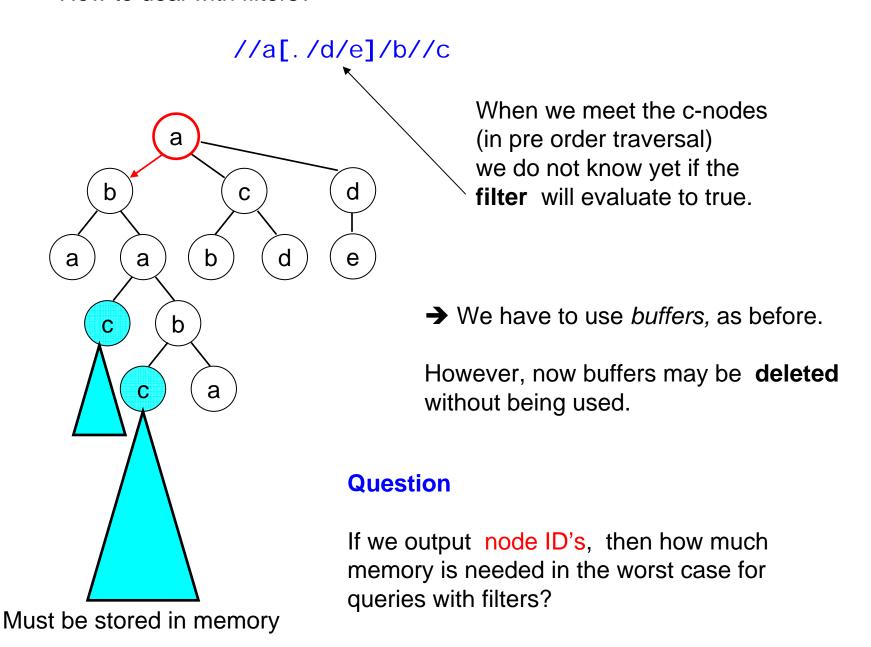

3. The Size of the DFA

Theorem [GMOS'02] The number of states in the DFA for one linear XPath expression P is at most:

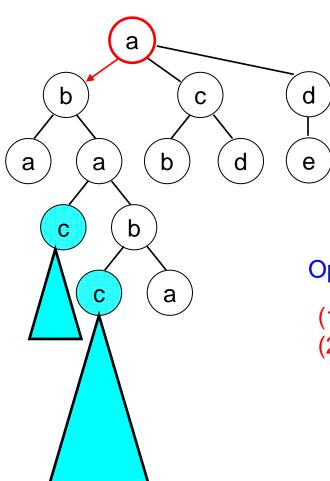

$$k+|P| k s^m$$

k = number of //
s = size of the alphabet (number of tags)
m = max number of * between two consecutive //

//a[./d/e]/b//c

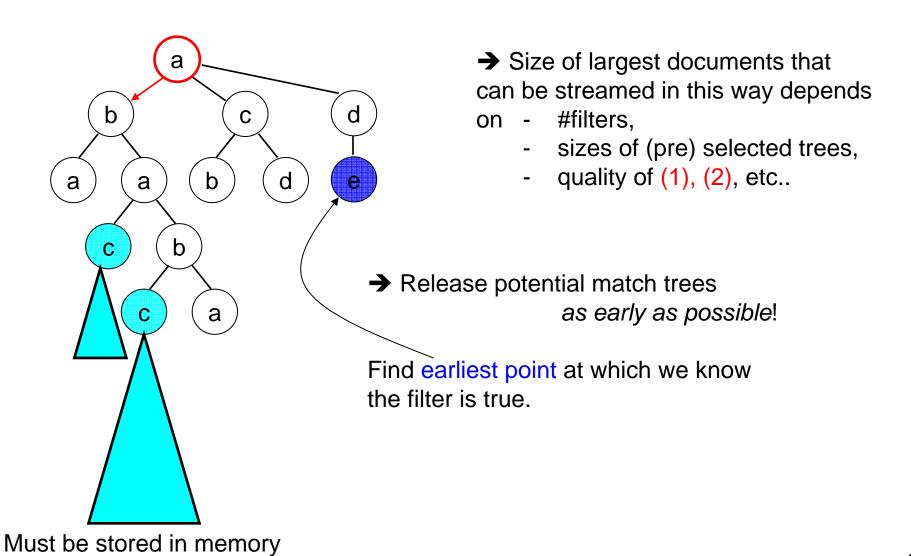

- → Size of largest documents that can be streamed in this way depends
- on #filters,
 - sizes of (pre) selected trees,
 - quality of (1), (2), etc..

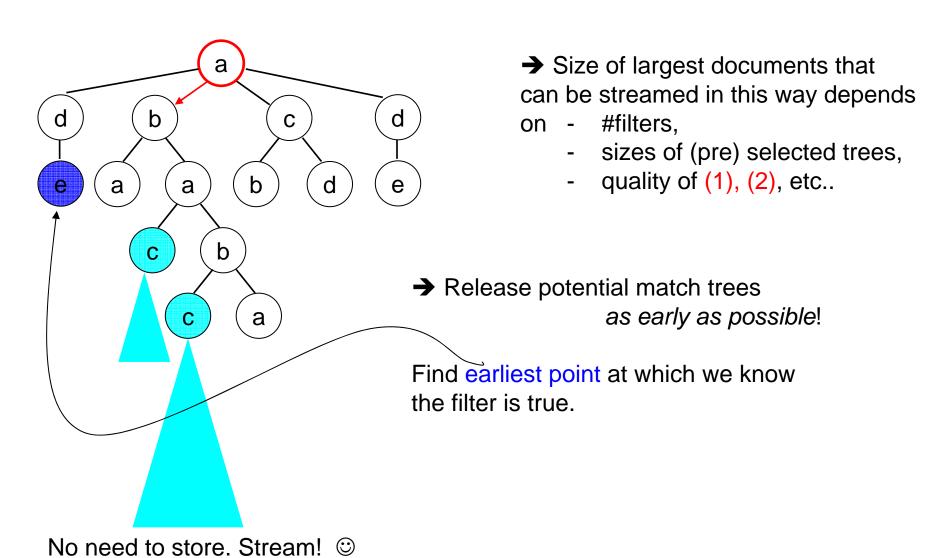

Optimizations

- (1) Store potential match trees as DAGs
- (2) Release potential match trees as early as possible!

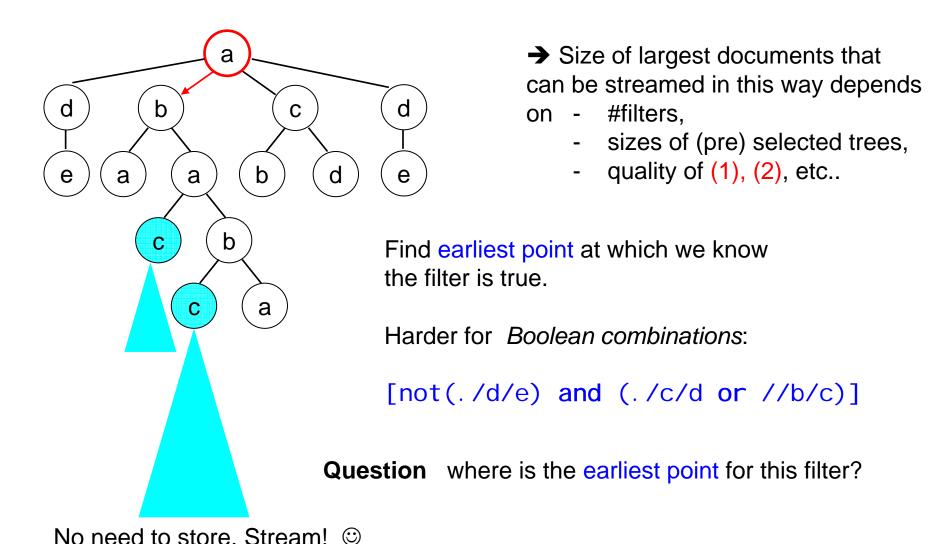

//a[./d/e]/b//c

//a[./d/e]/b//c

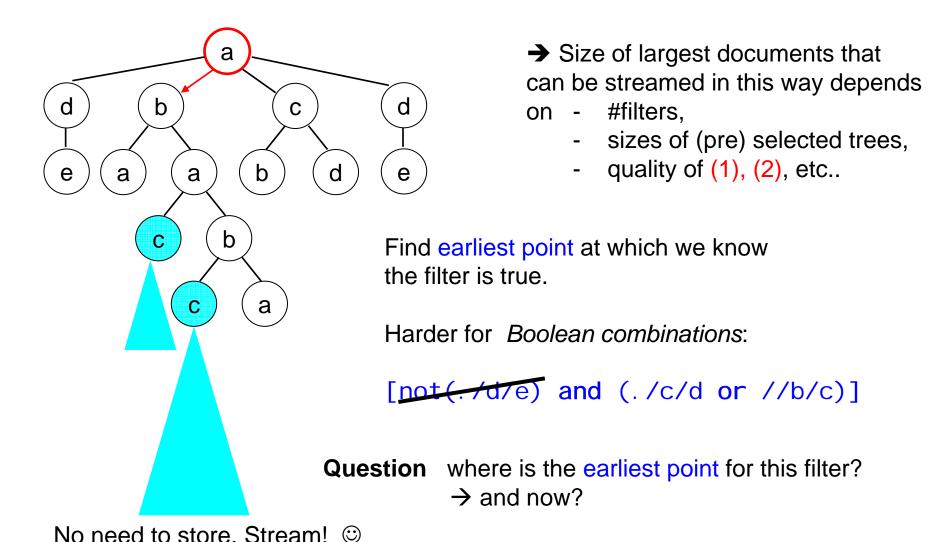

//a[./d/e]/b//c

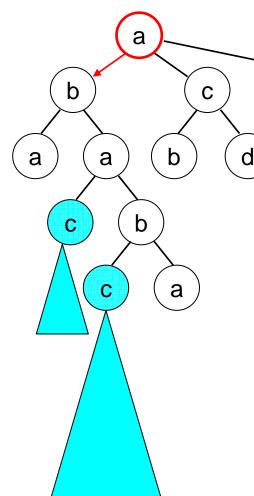

50

//a[./d/e]/b//c

//a[./d/e]/b//c

- → Size of largest documents that can be streamed in this way depends
- on #filters,
 - sizes of (pre) selected trees,
 - quality of (1), (2), etc..

We can also construct automata for filter expressions!

Use a *push-down* for potential candidates.

Push-Down Automaton

can probably be designed so that it pops/outputs candidates as early as possible.

Another Idea

Use **2-pass algorithm**: first (bottom-up) phase to mark subtrees with filter information.

Second (top-down) phase to determine match nodes.

Why is this interesting?

- → Fast main memory evaluation
- → Use disk as intermediate store (stream twice)

5. Streaming XPath Algorithms

- XFilter and YFilter [Altinel and Franklin 00] [Diao et al 02]
- X-scan [Ives, Levy, and Weld 00]
- XMLTK [Avila-Campillo et al 02]
- XTrie [Chan et al 02]
- SPEX [Olteanu, Kiesling, and Bry 03]
- Lazy DFAs [Green et al 03]
- The XPush Machine [Gupta and Suciu 03]
- XSQ [Peng and Chawathe 03]
- TurboXPath [Josifovski, Fontoura, and Barta 04]

-- From XPath (XP{[],/,//,*) to NFA --

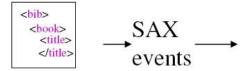

```
/catalog/product[category="tools"]/quantity
/catalog//product[category="kitchen"]/quality
//price
```

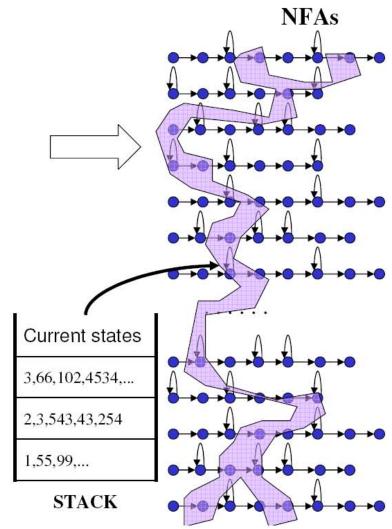

NFA-based XPE Processing

XPath

/bib/book /publisher="MK" /bib/book [category="recent"]/title /bib/book //address//*/zip="123" /bib/book //address//*="Galaxy" /bib/book /category="recent" /bib/book /address="123" /bib/book /address /field="567" /bib/book /tag="some" /bib/book [category="recent"]/title /bib/book //address//*="Seattle" /bib/book //address//*="Galaxy" /bib/book /category="recent" /bib/book /address="Lisbon" /bib/book /address /field="some" /bib/book/publisher="AW" /bib/book [category="recent"]/title /bib/book //address//*="123" /bib/book //address//*="Galaxy" /bib/book /category="new" /bib/book /address="London" /bib/book /address /field ="some" /bib/book/category ="old"

Basic NFA Evaluation

Properties:

- © Space = linear
- Throughput = decreases linearly

Systems:

- XFilter [Altinel&Franklin'99], YFilter.
- XTrie [Chan et al.'02]

DFA-based XPE Processing

DFA XPath /bib/book /publisher="MK" /bib/book [category="recent" Vtitle /bib/book //address//*/zip="123" /bib/book //address//*="Galaxy" /bib/book /category="recent" /bib/book /address="123" /bib/book /address /field="567" /bib/book /tag="some" /bib/book [category="recent"]/title /bib/book //address//*="Seattle" /bib/book //address//*="Galaxy" /bib/book /category="recent" /bib/book /address="Lisbon" /bib/book /address /field="some" . . . /bib/book/publisher="AW" /bib/book [category="recent"]/title /bib/book //address//*="123" /bib/book //address//*="Galaxy" /bib/book /category="new" /bib/book /address="London" /bib/book /address /field = "some" Current state /bib/book/category ="old" 399 552 <bib> SAX <book> </bib> events STACK

Basic DFA Evaluation

Properties:

- Throughput = constant!
- ⊗ Space = GOOD QUESTION

System:

XML Toolkit [University of Washington]
 http://xmltk.sourceforge.net

The Size of the DFA

Theorem [GMOS'02] The number of states in the DFA for one linear XPath expression P is at most:

$$k+|P| k s^m$$

k = number of //
s = size of the alphabet (number of tags)
m = max number of * between two consecutive //

Size of DFA: Multiple Expressions

```
//section//footnote
//table//footnote
//figure//footnote
....
//abstract//footnote

2<sup>100</sup> states !!
```

There is a theorem here too, but it's not useful...

Solution: Compute the DFA Lazily

- Also used in text searching
- But will it work for 10⁶ XPath expressions ?
- YES!
- For XPath it is provably effective, for two reasons:
 - XML data is not very deep
 - The nesting structure in XML data tends to be predictable

Duality -> XML databases -> XML streams

Lazy DFA DFA, view class: XP{/,//,*}

Features

- Sharing the process of / and //, * and tag
- DFA-based
- Compute DFA lazily (on demand)
- # of DFA states
 - Independent from # of XPath exprs.
 - Depends on DataGuide size (schema)

Issue

Predicates: XPush machine [SIGMOD'03]

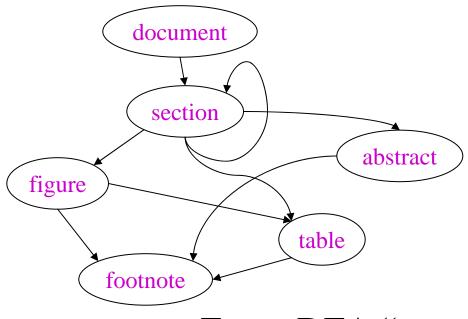

- Document Type Definition (DTD)
 - Part of the XML standard
 - Will be replaced by XML Schema
- Example DTD:

```
<!ELEMENT document (section*)>
<!ELEMENT section ((section|abstract|table|figure)*)>
<!ELEMENT figure (table?,footnote*)>
. . . . .
```

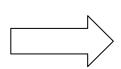

Definition A DTD is simple if all cycles are loops

Simple DTD:

XPath expressions

//section//footnote
//table//footnote
//figure//footnote
//abstract//footnote

Eager DFA "remembers" 2⁴ sets Lazy DFA "remembers" only 4 sets

Theorem [GMOS'02] If the XML data has a "simple" DTD, then lazy DFA has at most:

$$1+D(1+n)^d$$

states.

n = max depths of XPath expressions

D = size of the "unfolded" DTD

d = max depths of self-loops in the DTD

Fact of life:

"Data-like" XML has simple DTDs

Lazy DFA and Data Guides

- "Non-simple" DTDs are useless for the lazy DFA
- "Everything may contain everything"

```
<!ELEMENT document (section*)>
<!ELEMENT section ((section|table|figure|abstract|footnote)*)>
<!ELEMENT table ((section|table|figure|abstract|footnote)*)>
<!ELEMENT figure ((section|table|figure|abstract|footnote)*)>
<!ELEMENT abstract ((section|table|figure|abstract|footnote)*)>
```

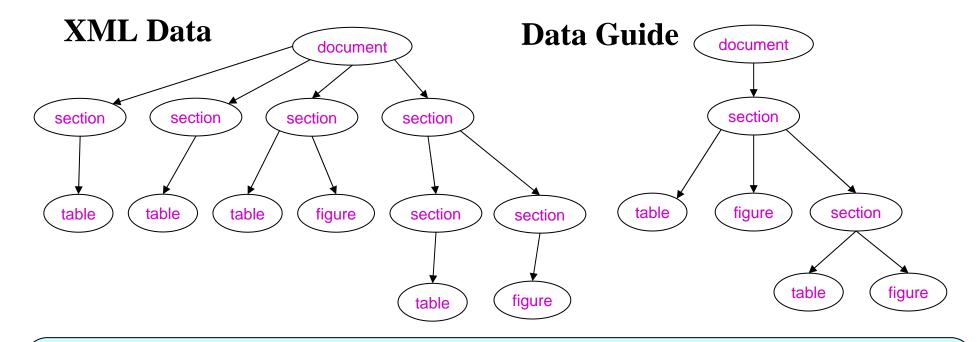

Fact of life: "Text"-like XML has non-simple DTDs

Lazy DFA and Data Guides

Definition [Goldman&Widom'97]

The data guide for an XML data instance is the Trie of all its root-to-leaf paths

Lazy DFA and Data Guides

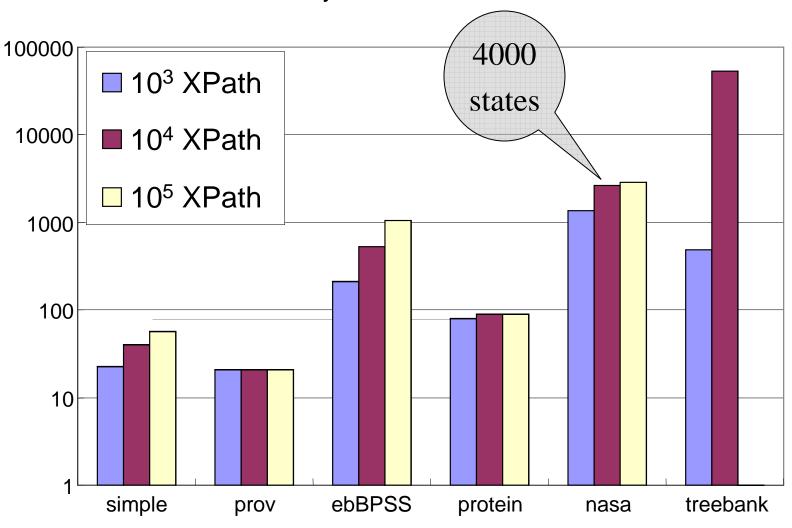

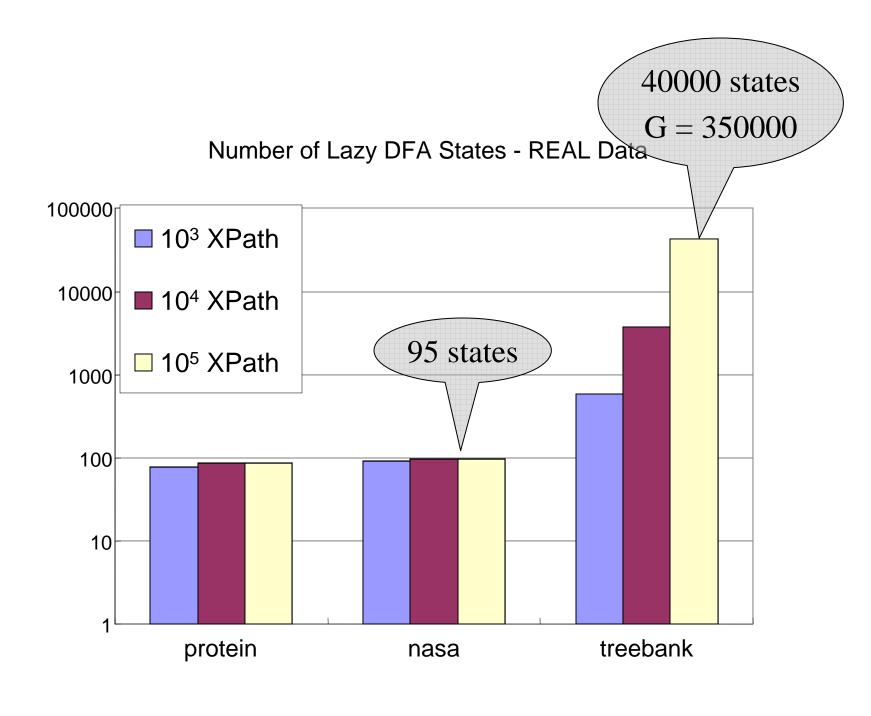

Fact of life: real XML data has "small" data guide [Liefke&S.'00]

Theorem [GMOS'02] If the XML data has a data guide with G nodes, then the number of states in the lazy DFA is at most:

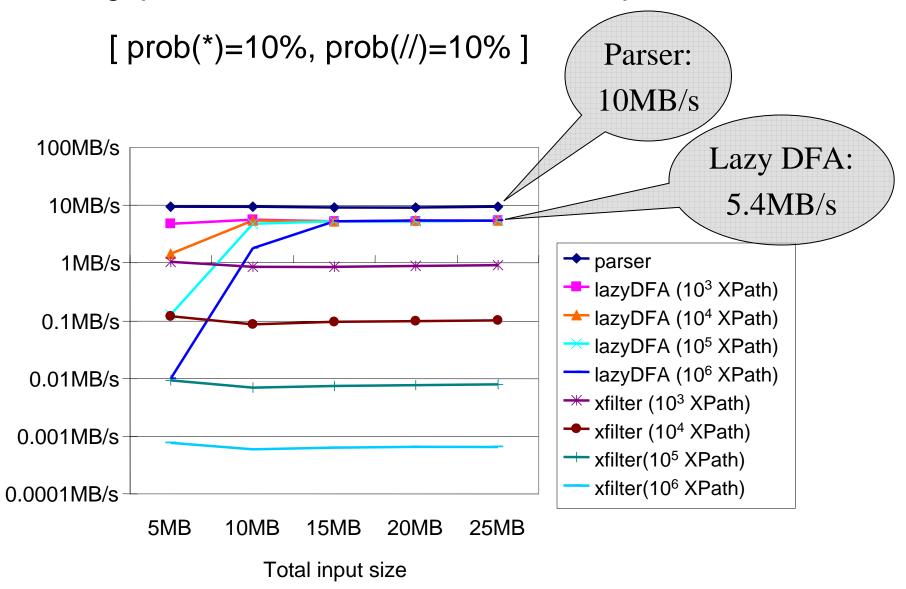

G = number of nodes in the data guide

Number of Lazy DFA States - SYNTHETIC Data

Throughput for 10³, 10⁴, 10⁵, 10⁶ XPath expressions

END Lecture 9
