Week 10

Recap from last week

- ➊ Using automata to run queries in streaming

Recap from last week

- ① Using automata to run queries in streaming
- ② Handling filters with upward axes

Recap from last week

- ① Using automata to run queries in streaming
- ② Handling filters with upward axes

Recap from last week

- ➊ Using automata to run queries in streaming
- ➋ Handling filters with upward axes

Today

- How to add preceding-sibling/following-sibling ?
- What data structures to use for automata ?

Following-sibling

Fundamentally, not very different from `child`!

In a pre-order traversal:

`child` : From a node, go `firstChild` then `nextSibling`, ..., `nextSibling` until `NULL` is found

`following-sibling` : From a node, go `nextSibling`, ..., `nextSibling` until `NULL` is found

Following-sibling

Fundamentally, not very different from `child`!

In a pre-order traversal:

`child` : From a node, go `firstChild` then `nextSibling`, ..., `nextSibling` until `NULL` is found

`following-sibling` : From a node, go `nextSibling`, ..., `nextSibling` until `NULL` is found

What does it mean in terms of automata?

Following-sibling

Fundamentally, not very different from `child`!

In a pre-order traversal:

`child` : From a node, go `firstChild` then `nextSibling`, ..., `nextSibling` until `NULL` is found

`following-sibling` : From a node, go `nextSibling`, ..., `nextSibling` until `NULL` is found

What does it mean in terms of automata?

Add a new *kind* of transition

Example

//a/b//d

Example

Example

//a/following-sibling::b//d?

Example

//a/following-sibling::b//d?

Example

//a/following-sibling::b//d?

When we evaluate an automaton we can perform two kinds of transitions:

- When doing a “first child” move, we take black transitions (Down)
- When doing a “next sibling” move, we take red transitions (Right)

Example

$\{1\}, \{\}$

Initially, the stack contains the initial state

Example

$\{1\}, \{\}$
 $\{1\}, \{\}$

`startElement("c")`, one Down transition, no Right transition

Example

$\{1\}, \{\}$
 $\{1\}, \{\}$
 $\{1\}, \{\}$

`startElement("d")`, one Down transition, no Right transition

Example

$\{1\}, \{\}$
$\{1\}, \{\}$

`endElement("d")`, replace last-sibling with the top of the stack

Example

$\{1\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

`startElement("a")`, one Down transition, one Right transition

Example

$\{1\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

the Right transition goes to state 2, update the right of the stack

Example

$\{1\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

the Down transition goes to state 1, pushed on the stack

Example

$\{1,3\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

`endElement("a")`

Example

$\{1,3\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

From $\{1\} \cup \{2\}$ compute the b transition

Example

$\{1,3\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

One Right (stay in state 2), replace right part of stack

Example

$\{1,3\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

Two Down (stay ins state 1, go to state 3), push on the stack

Example

$\{1,3\}, \{\}$
 $\{1,3\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

Example

$\{1,3\}, \{\}$
 $\{1,3\}, \{\}$
 $\{1,3\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

Example

$\{1,3\}, \{\}$
 $\{1,3\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

Example

$\{1,3,4\}, \{\}$
 $\{1,3\}, \{\}$
 $\{1,3\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

Example

$\{1,3\}, \{\}$
 $\{1,3\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

Example

$\{1,3\}, \{\}$
 $\{1,3\}, \{\}$
 $\{1,3\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

Example

$\{1,3\}, \{\}$
 $\{1,3\}, \{\}$
 $\{1,3\}, \{\}$
 $\{1\}, \{2\}$
 $\{1\}, \{\}$

Example

$\{1,3,4\}, \{ \}$
 $\{1,3\}, \{ \}$
 $\{1,3\}, \{ \}$
 $\{1\}, \{2\}$
 $\{1\}, \{ \}$

Path with following-sibling and no filters

Adapt last week's algorithm:

- keep a stack of pairs of sets of states
- the first set of states represents the states of the parent
- the second set of states represents the states of the previous-sibling

Path with following-sibling and no filters

Adapt last week's algorithm:

- keep a stack of pairs of sets of states
- the first set of states represents the states of the parent
- the second set of states represents the states of the previous-sibling

More precisely, on `startElement`

- 1 Take the top of the stack $S_{\text{parent}}, S_{\text{presib}}$;
- 2 Compute the union $S = S_{\text{parent}} \cup S_{\text{presib}}$
- 3 Compute two new sets S'_{parent} and S'_{presib}
- 4 S'_{parent} is the set of states that can be reached from S with a `Down` transition S'_{presib} is the set of states that can be reached by a `Right` transition
- 5 At the top of the stack, replace S_{presib} with S'_{presib}
- 6 Push $S'_{\text{parent}}, \{\}$ at the top of the stack

Adding preceding-sibling in filters

Consider `//a//b[./parent::c/preceding-sibling::d]/c`.
What can we say about the b nodes ?

- They must have a parent c
- The parent must have a preceding-sibling d

This is true for all the nodes which are:

- below a c
- which is a following sibling of a d
- which can occur anywhere

⇒ `//d/following-sibling::c/*`

Only need to adapt last week's algorithm to following-sibling

Some more examples of rewriting of filters

`[./ancestor::d/preceding-sibling::e/parent::f]`

becomes

`//f/e/following-sibling::d/*`

Some more examples of rewriting of filters

`[./ancestor::d/preceding-sibling::e/parent::f]`

becomes

`//f/e/following-sibling::d/*`

`[./preceding-sibling::e/ancestor::d/preceding-sibling::f]`

becomes

`//f/following-sibling::d//e/following-sibling::*`

Some more examples of rewriting of filters

`[./ancestor::d/preceding-sibling::e/parent::f]`

becomes

`//f/e/following-sibling::d/*`

`[./preceding-sibling::e/ancestor::d/preceding-sibling::f]`

becomes

`//f/following-sibling::d//e/following-sibling::*`

What is the general rule ?

Rewriting backward filters

Let $[f]$ be a filter with backward axes. We rewrite it into a path d . d and f do *NOT* compute the same results but, for every node selected by d , $[f]$ is true. Let:

$$f = ./a_0::t_0/a_1::t_1/\dots/a_n::t_n$$

where $a_i \in \{\text{parent, ancestor, preceding-sibling}\}$ and t_i is a label or $*$.

$$//t_n/\bar{a}_n::t_{n-1}/\dots/\bar{a}_0::*$$

where \bar{a}_i is the inverse axis of a_i (parent is the inverse of child, descendant the inverse of ancestor and preceding-sibling the inverse of following-sibling)
