

DPST1092 23T2 – Bitwise Operators

<https://www.cse.unsw.edu.au/~dp1092/23T2/>

Bitwise Operators

Everything in C really is just 1's and 0's under the hood!

- eg. the number 42 is 0b00101010
- eg. the ascii character '#' is 0b00100011
- eg. the floating point 3.14 is 0b01000000010010001111010111000011

C provides 6 operators which operate on individual bits of values

```
x & y      // bitwise and
x | y      // bitwise or
x ^ y      // bitwise exclusive-or (XOR)
~ x        // bitwise not
x << n     // left shift
x >> n    // right shift
```

Bitwise AND: &

The **&** operator

- takes two values (1,2,4,8 bytes), treats as sequence of bits
- performs logical AND on each corresponding pair of bits
- result contains same number of bits as inputs

Example:

$$\begin{array}{r} 00100111 \\ \& 11100011 \\ \hline 00100011 \end{array} \quad \begin{array}{c|cc} \text{AND} & 0 & 1 \\ \hline & - - - & - - - - \end{array}$$

Used for e.g. checking whether a bit is set

Checking for Odd Numbers

The obvious way to check for odd numbers in C

```
int is_odd(int n) {
    return n % 2 != 0;
}
```

We can use **&** to achieve the same thing:

```
int is_odd(int n) {
    return n & 1;
}
```

Bitwise OR: |

The **|** operator

- takes two values (1,2,4,8 bytes), treats as sequence of bits
- performs logical OR on each corresponding pair of bits
- result contains same number of bits as inputs

Example:

00100111	OR	0	1
11100011	---	- - - -	
-----		0	0 1
11100111		1	1 1

Used for e.g. ensuring that a bit is set

Bitwise NEG: ~

The **~** operator

- takes a single value (1,2,4,8 bytes), treats as sequence of bits
- performs logical negation of each bit
- result contains same number of bits as input

Example:

~ 00100111	NEG	0	1
-----	---	- - - -	
11011000			1 0

Used for e.g. creating useful bit patterns

Bitwise XOR: ^

The **^** operator

- takes two values (1,2,4,8 bytes), treats as sequence of bits
- performs logical XOR on each corresponding pair of bits
- result contains same number of bits as inputs

Example:

00100111	XOR 0 1
\wedge 11100011	----- -----
-----	0 0 1
11000100	1 1 0

Used in e.g. generating hashes, graphics operations, cryptography

Exercise: Bit Operations

What are the values of the following:

- $(01010101 \ \& \ 10101010)$
- $(01010101 \ | \ 10101010)$
- $(x \ \& \ \sim x)$
- $(x \ | \ \sim x)$

Assume we have a variable `uint8_t x`. Write a line/s of code to

- set the 3rd least significant bit to 1
- set the 3rd least significant bit to 0

Left Shift: <<

The **<<** operator

- takes a single value (1,2,4,8 bytes), treats as sequence of bits
- also takes a small positive integer x
- moves (shifts) each bit x positions to the left
- left-end bit vanishes; right-end bit replaced by zero
- result contains same number of bits as input

Example:

00100111 << 2	00100111 << 8
-----	-----
10011100	00000000

Right Shift: >>

The >> operator

- takes a single value (1,2,4,8 bytes), treats as sequence of bits
 - also takes a small positive integer x
 - moves (shifts) each bit x positions to the right
 - right-end bit vanishes; left-end bit replaced by zero(*)
 - result contains same number of bits as input

Example:

00100111 >> 2	00100111 >> 8
-----	-----
00001001	00000000

- shifts involving negative values are not portable (implementation defined)
 - common source of bugs in CP1521 and elsewhere
 - always use unsigned values/variables to be safe/portable.

Exercise: Shifts

Given the declaration: `uint8_t x = 19`. What is the value of

- $x \gg 2$
 - $x \ll 1$

Write code to

- multiply x by 4 using bit shift operations.
 - divide x by 8 using bit shift operations.
 - calculate 2 power of n, for a given n.
 - print out a given uint8_t in binary.

shift as multiply.c: using shift to multiply by 2^n

```
$ gcc shift_as_multiply.c print_bits.c -o shift_as_multiply
$ ./shift_as_multiply 4
2 to the power of 4 is 16
In binary it is: 0000000000000000000000000000100000
$ ./shift_as_multiply 20
2 to the power of 20 is 1048576
In binary it is: 00000000001000000000000000000000
$ ./shift_as_multiply 31
2 to the power of 31 is 2147483648
In binary it is: 10000000000000000000000000000000
$
```

print_bits.c: extracting the n-th bit of a value

```
// print the bottom how_many_bits bits of value
void print_bits(uint64_t value, int how_many_bits) {
    // print bits from most significant to least significant
    for (int i = how_many_bits - 1; i >= 0; i--) {
        int bit = get_nth_bit(value, i);
        printf("%d", bit);
    }
}

// extract the nth bit from a value
int get_nth_bit(uint64_t value, int n) {
    // shift the bit right n bits
    // this leaves the n-th bit as the least significant bit
    uint64_t shifted_value = value >> n;
    // zero all bits except the the least significant bit
    int bit = shifted_value & 1;
    return bit;
}
```

set_bit_range.c: using << and - to set a range of bits

```
$ gcc set_bit_range.c print_bits.c -o set_bit_range
$ ./set_bit_range 0 7
Bits 0 to 7 of 255 are ones:
00000000000000000000000011111111
$ ./set_bit_range 8 15
Bits 8 to 15 of 65280 are ones:
00000000000000001111111100000000
$ ./set_bit_range 8 23
Bits 8 to 23 of 16776960 are ones:
0000000011111111111111000000000
$ ./set_bit_range 1 30
Bits 1 to 30 of 2147483646 are ones:
01111111111111111111111111111110
```

set_bit_range.c: using << and - to set a range of bits

```
int low_bit = strtol(argv[1], NULL, 0);
int high_bit = strtol(argv[2], NULL, 0);
uint32_t mask;
int n_bits = 8 * sizeof mask;

int mask_size = high_bit - low_bit + 1;
mask = 1;
mask = mask << mask_size;
mask = mask - 1;
mask = mask << low_bit;
printf("Bits %d to %d of %u are ones:\n", low_bit, high_bit, mask);
print_bits(mask, n_bits);
printf("\n");
```

source code for set_bit_range.c

extract_bit_range.c: extracting a range of bits

```
$ gcc extract_bit_range.c print_bits.c -o extract_bit_range
$ ./extract_bit_range 4 7 42
Value 42 in binary is:
0000000000000000000000000000101010
Bits 4 to 7 of 42 are:
0010
$ ./extract_bit_range 10 20 123456789
Value 123456789 in binary is:
00000111010110111100110100010101
Bits 10 to 20 of 123456789 are:
11011110011
```
